

BASELINE ANALYSIS OF VASCULAR VEGETATION
FOR HISTORIC OAK SAVANNA REMNANTS OF NORTHERN ILLINOIS

INTRODUCTION

Fire has played a major and integral role in the evolution, development, and maintenance of many biological systems throughout North American (Ahlgren, 1960; Wright, 19--). But however, only recently, has a basic understanding of the intricate role of fire in maintaining grasslands, wetlands, and numerous forest types (Kilgore, 1978, 1983; Hinselman, 1973) developed. Equally as recent is the understanding that fire suppression associated with Eurasian settlement of North America has resulted in gross changes in the aspect, appearance, and ecological functions of natural systems.

Society's long-standing concept of fire as an undesirable, destructive agent now is being enlightened by the scientific community (Kilgore, 1982). Results from research in systems where fire has played an important historic role suggest fire suppression is often followed by declines in native plant and animal species richness and diversity, increased litter and shading, phytotoxin build up in substrates, decreased availability of essential nutrients and mycorrhizal fungi, and increased homogeneity in habitat structure and spatial heterogeneity. The increased biomass and fuel loads than can develop eventually can produce severe conflagrations and cause even more potential disruption. Reduced nutrient cycling and increased domination by few species also can result (Huston, 1979). In some forest types, shifts in many wildlife species, and increases in shade tolerant and less flammable plant species accompany fire suppression (Hinselman, 1973; Laucks, 1970; Ahlgren, 1960; Apfelbaum and Haney, 1981; Schmelz et al., 1975; Schlesinger, 1976; Davison, 1980; McGee, 1984).

Savanna ecosystems have a global distribution in temperate, subtropical, and tropical climes (Walter, 1973). Most are associated as

peripheral zones with grassland and sometimes forested ecosystems (Walter, 1973; Anderson, 1982). The proximity of savanna to grasslands with frequent recurring fires may suggest an important historic role for fire in savanna and also as well as some forests. Physiologic responses and adaptations of some prairie and savanna species suggests that they were dependent upon fire and that fire had a critical role in the synecology of their biomes.

The historical occurrence of fire in the upper midwest prairies and associated savannas, barrens, and oak woodlands is well documented (Curtis, 1959). The role of this natural process in development and maintenance of these communities also has had a considerable historical treatment and review (Gleason, 1912, 1913; Muir, 1913; Wells, 1970; Vogl, 1974, Anderson, 1982, 1983; Nuzzo, 1986). The vegetational character of post-settlement savannas, barrens, and oak woodlands has been studied (Vestal, 1936; Bray, 1960; Curtis, 1959), but very little specific pre-settlement detail on this biological community is known (Packard, 1985).

Prairie, oak savanna, and oak woodland often originally were contiguous communities (Anderson, 1982) and certainly influenced on a landscape level by widespread natural processes such as fire. Prescribed burning has been the primary prairie management tool used in Illinois for nearly a decade; but only recently have efforts been made to use fire for the maintenance and restoration of oak woodlands and savannas. Although some examples of these communities have been maintained naturally on sand substrates, their counterparts on silt loam soils began to disappear with settlement and subsequent fire suppression. Only a few silt loam savanna remnants of even moderate quality now remain., and these woodlands are typically in transition to domination by more mesic woody species as canopy oaks decline. The pre-settlement flora and fauna of these communities have changed greatly; management and restoration efforts need study to document these

changes and to develop potential maintenance options for existing remnants.

In northern Illinois, the original distribution of savanna has been mapped only on a general or partial basis (Nuzzo, 1986; Moran, 1978; Hanson, 1978). This community occupied deep silt loam soils, primarily on moraines, and was a frequent vegetation type in northern Illinois. The pre-settlement savanna vegetation in this region now has all but been lost to agricultural land-uses including great modifications by timbering, tillage, drainage, intense recurring livestock grazing, and fire suppression. Several degraded silt loam soil savannas remain, but most remnants occur on sandy soils.

The Illinois Nature Preserve Commission recognized the urgency of this problem and contracted with The Morton Arboretum to collect baseline vegetation information and study the effects of burning on plants, small mammals, and insects at Reed-Turner Nature Preserve, Lake County, a 15 ha closed oak woodland community. Additional funding from the Nature Conservancy, Max McGraw Foundation, Lake County Forest Preserve District, and Illinois Department of Conservation (Non-game Checkoff Fund) allowed expansion of the study to cover three other sites representing a mesic continuum from closed to open savanna conditions. These included Middlefork Savanna (Lake County), a 10 ha high quality open savanna; Somme Prairie and Savanna (Cook County), a 45 ha matrix of prairie and closed savanna; and Wadsworth Prairie and Savanna (Lake County), a 40 ha closed oak savanna with some adjacent prairie. Similar studies of dry-mesic and wet-mesic savanna have not been initiated.

Goals of these investigations included:

- 1) Characterization of quantitative and qualitative aspects of the vascular vegetation, nesting birds, resident small mammals, and selected insects in the study areas.

- 2) Establishment of baseline monitoring and research designed to allow an analysis of the effects of prescribed burning on these various plant and animal communities.
- 3) Characterization of the effects of prescribed burning on the study areas, comparison of differences within and among sites, and development of long-term management recommendations to rehabilitate these sites.

Specific vegetation objectives are to determine the effect of burning on (1) the composition of the herbaceous (fine fuel) layer (does fire result in an increase in fuel species and decline in other species?); (2) the density of invading woody species (does fire cause a decline in woody density?); (3) oak reproduction (does fire result in increased reproduction of oaks?); and (4) does the natural quality and species richness increase over time. Significant data may not be immediately available on oak reproduction, but initial trends for herbaceous/fuel species and woody density should begin to become established after several years of fire treatment.

We expect resulting vegetation changes to have significant effects on wildlife. If tree and shrub layers are opened by fire, shifts in bird and small mammal populations should occur: will species of these closed forest communities decline while open ground foraging species increase? Similarly, will fire cause an increase in those insect populations adapted to exposed ground conditions and high density/diversity of grass/sedge and forb species, and will ground fires result in direct mortality of some insect species adapted to fire exclusion?

STUDY AREAS

REED-TURNER WOODLAND

The Reed-Turner Preserve was chosen because of the existence of a high quality woodland which included remnants of historic savanna vegetation. Barbara Turner, Preserve owner endorsed the project, and use of an existing trail system facilitated access and segmentation of experimental units.

This 15 ha Preserve is located on the edge on the historic Long Grove (Figure 1). Presumably, Reed-Turner Woodland was originally a savanna. The Public Land Survey and map of Section 24 (Figure 2) described the western border as "timber" and "scattering timber" with an understory of young oak and hazel. Witness trees and line trees all were bur and white oaks with diameters between 9 and 24 inches. Black oak, red oak, and hickory also are mentioned for this section.

Previous preserve studies included a master plant (INPC, 1979) vegetation surveys (Schulenberg, unpublished data; Wilhelm and Packard, unpublished data) and studies of butterflies (Shennum, unpublished data).

These studies suggested that Reed-Turner Woodland, like most former prairie groves, had gradually lost its open structure and many of its species. Now, a variety of community types including dry-mesic and mesic upland forest with north- and south-facing slopes, and floodplain (wet-mesic) forest occur within the preserve. Oak reproduction appears minimal in all areas, although old, open grown bur and white oaks occur on the preserve's south boundary where a natural prairie-savanna transition occurred. A small 1/2 acre area adjacent to the north preserve boundary was kept open by mowing for many years. This area is of particular interest because of an inclusion of savanna vegetation including alumroot (*Heuchera richardsonii*), shooting star (*Dodecatheon meadia*), fire pink (*Silene virginica*), two-flowered cynthia (*Krigia biflora*), and the state-threatened

creamy vetchling (Lathyrus ochroleucus). Elsewhere in the preserve are local populations of other savanna species including sandwort (Arenaria lateriflora), wild hyacinth (Camassia scilloides), and Pennsylvania sedge (Carex pensylvanica).

WADSWORTH SAVANNA

Wadsworth Savanna is a 40 ha closed canopy savanna remnant, which is part of the larger (over 120 ha) Wadsworth Prairie Nature Preserve, Lake County, Illinois (Figure 1). The preserve is owned by the Lake County Forest Preserve District and managed by prescribed burning. The site was chosen because it was presumed to represent the closed end of a continuum from open to closed savanna, and because of management potential by the preserve owner.

The Nature Preserve is a complex of prairie, wetland, and savanna situated adjacent to the east side of the Des Plaines River. Most of the preserve occurs in the River floodplain; however, the savanna study site is situated on a low morainic bluff adjacent to the floodplain.

No prior investigations have been conducted at the site. Qualitative assessments suggested that part of the savanna had been more degraded by past grazing but primary changes appear to have been an increase in density of woody understory vegetation due to fire protection. Bur oak is a common overstory tree, while black cherry is a major understory tree. Herbaceous savanna species noted initially included Lathyrus ochroleucus, Taenidia integerrima, Zizia aurea, and Carex pensylvanica. Included within the site are several sedge-dominated wetlands, while immediately adjacent tracts includes a high quality prairie remnant and sedge meadow.

SOMME PRAIRIE AND SAVANNA

Somme Prairie and Savanna is a 40 ha tract containing a small area of closed oak savanna, and more extensive degraded prairie openings within a matrix of successional woody vegetation. This site is owned by the Cook County Forest Preserve District and managed by the North Branch Prairie Project. It was chosen for study because an accelerated conversion to open higher quality savanna is being managed for by brush clearing, seeding, and prescribed burning. A control (non-burn) treatment was established in a separate Forest Preserve District tract adjacent to the east.

The North Branch Prairie Project has conducted some prior studies (S. Packard, pers. comm.) at the site. These qualitative studies and observations found many weedy plant species and a low diversity of prairie and savanna species in openings. A closed former savanna community now characterized by bur oak with an understory dominated by buckthorn occurs along the south tract boundary and in adjacent Forest Preserve property. Included within the Forest Preserve, but not the study area is a small high quality prairie dedicated as Somme Prairie Nature Preserve.

MIDDLEFORK SAVANNA

Middlefork Savanna is a 10 ha tract of relatively high quality savanna in Lake County, Illinois (Figure 1); it apparently is the best remnant on silt loam soil in Illinois. The area remains in private ownership but public protection and management is being negotiated. The site was chosen as a benchmark for comparison against more disturbed sites in the study complex. Past disturbances to Middlefork Savanna include moderate grazing and invasion by Eurasian buckthorn. The site includes a railroad right-of-way and prairie which may have served as a source of periodic fire and recolonization by prairie species after grazing.

The site was recently discovered, and no prior quantitative studies have been completed. Most vegetative information on the site was collected during the 1986 study season. The entire site was burned for management purposes in spring, 1985.

GENERAL METHODS

REED-TURNER WOODLAND

The small size (15 ha) of the preserve allowed for relatively intense sampling but not for a wide variety of treatments. To provide control for spatial variability and management treatments the preserve was segmented into east, west, and center woods, and unmowed yard study areas and each was further divided into burn and non-burn units (Figure 3). Segmentation into burn units followed trail systems.

Plant species lists for control and test areas were developed following the time-meander search technique of Goff et al. (1982). Lists were generated from two simultaneous surveys through each study segment by recording all plant species observed in five-minute search intervals until no additional species were listed. This method established a datum from which to judge the effectiveness of sampling. An east-west preserve baseline was established, from which perpendicular sampling transects were surveyed through treatment and control areas for each site study unit. These random stratified transects also were perpendicular to major drainage gradients in the preserve. Study transect endpoints and 50m points were marked with steel conduit stakes.

WADSWORTH SAVANNA

In order to represent presumed differences between effects of past

grazing, the study site was divided into two replicates; each replicate will receive burn and non-burn treatments. Four east-west 300 meter transects were established (Figure 4), each in a separate burn or non-burn replicate. Transects were stratified randomly by positioning their starting points along a north-south railroad track baseline at the west boundary of the study site.

SOMME PRAIRIE AND SAVANNA

Four east-west 780 meter transects were surveyed on a stratified random basis from a northwest-coutheast baseline located along the east preserve boundary (Figure 5). Two transects were extended 300 meters eastward as control (non-burn) transects in an adjacent forest preserve.

MIDDLEFORK SAVANNA

A baseline for transect locations was positioned along the railraod tracks forming the west site boundary. Four transects were surveyed on a stratified random basis from the baseline and extended east for distances of 150, 150, 100, and 50 meters (Figure 6). The irregular shape of the area determined the various lengths of transects.

SPECIFIC METHODS

GROUND COVER

All vascular and woody plants less than a meter high were quantified in meter square quadrats centered over transect lines at 10 meter intervals. In each quadrat percent cover of all plant species and ground cover elements (woody debris, leaf litter, rock, etc.) was estimated within cover classes. This data was used to calculate absolute and relative cover, relative

frequency, and importance values for each species by transects. Transects were combined for control (non-burn) and treatment (burn) areas. All nomenclature for vascular vegetation follows Swink and Wilhelm (1979). Natural quality indexing (Swink and Wilhelm, 1976) of control and test areas were evaluated from quadrat data and species lists generated using the Goff (1982) method. Searches for special status species were conducted, and demographic and reproductive data was measured for these species.

All sampling was conducted in late May 1986; later blooming species were identified in vegetative condition. Plots were re-sampled in August 1986 to determine adequacy of vegetative identification and sampling; results were found to be virtually identical and are not reported here.

WOODY VEGETATION

The intercept of woody plant canopies directly over each 50m transect was recorded by species in two layers, trees (2 inches DBH and over) and vines, shrubs, and small trees (less than 2 inches DBH and greater than 1m high). All associated tree diameters (DBH) were recorded by species on 1m either side of each 50m line. Stems of all vine, shrub, and small tree species at least 1m tall were tallied within 1m of the left side of each 50m line. All dead stems were identified but recorded separately. Woody stems were divided into 4 inch size classes for each species. Alive and dead stems were expressed as species density and combined for all transects within burn and within non-burn treatments.

RESULTS

REED-TURNER WOODLAND

Ground Cover

Species richness generated by time meander searches for the center woods burn and non-burn units appears similar, with 52 species (13% were not native) (Table 1). Species richness was highest in the yard study area (92 species, 20% not native), with all species encountered in a short search time because of the small size of this area. Species richness also was high in the west woods study area (87 species, 17% not native), but more search-time was required to encounter all species in this larger area.

Thirty-six species were encountered in quadrats in the east woods study area (Tables 2 & 3), and burn and non-burn transects were similar. Dominant herbaceous plants were the woodland species *Circaea quadrangularis*, *Erythronium albidum*, and *Smilacina racemosa*. Dominant woody plants under 1 meter were *Fraxinus americana*, *Prunus serotina*, *Rhamnus cathartica*, *Rhamnus frangula*, *Ribes missouriense*, and *Cornus racemosa*. Fuel primarily was from leaf litter (Importance value = 62-66), but woody litter also was abundant (IV = 20-23).

Transect quadrat data was combined for the west woods and center woods study areas (Table 4 & 5) because of their small size and overlapping transects. Fifty-four species were encountered, and burn and non-burn transects were similar. Dominant herbaceous plants were *Circaea quadrangularis*, *Erythronium albidum*, *Smilacina racemosa*, and *Arisaema triphyllum*. The savanna species *Camassia esculenta* and *Carex pensylvanica* were relatively common on these transects, while *Dodecatheon meadia* and *Veronicastrum virginicum* were present but not sampled. Dominant woody plants under 1 meter were *Fraxinus americana*, *Cornus racemosa*, and *Prunus virginiana*. Fuel primarily was from leaf litter (IV = 64-66), but woody

litter also was abundant (IV = 21-24).

The yard study area had the relatively highest species diversity (Tables 6 & 7). Sixty-nine species were encountered in this small area. Erythronium albidum and Smilacina racemosa were common, but shared dominance with graminoid/cyperoid fuel species (IV = 14, and 20) including Carex sp., Carex pensylvanica, Danthonia spicata, Poa compressa, Poa pratensis, and other graminoid species such as European fine-leaved Fescues. Dominant woody plants under 1 meter were Fraxinus americana, Cornus racemosa, Rhamnus cathartica, and Quercus alba. Leaf litter was relatively low (IV = 2-30), as was woody litter (IV = 2-9).

Two colonies of the state-threatened plant species Lathyrus ochroleucus were encountered during the field survey. This legume was restricted to openings, which were free from understory competition by shrubs. The yard study area colony consisted of 14 ramets (3 flowering) in a 15 meter square area. This colony apparently had survived in a mowed yard for many years. A second colony occurred in a previously mowed opening in the center woods. This colony had 66 ramets in a 7 meter square area; 6 ramets apparently flowered but were destroyed by a herbivore.

Woody vegetation

For purposes of discussion, woody vegetation data from the three woody study areas were lumped into burn and non-burn data sets (Tables 8 & 9), and treated separately from the yard study area data set (Table 10).

Woody vegetation in the yard was virtually absent, with one Quercus alba in an upper size class; though, the other study areas had a complex canopy structure, which appeared similar on burn and non-burn sites.

Upper size classes (10-24 inches DBH) at Reed-Turner Woodland were dominated by Quercus alba; subordinate co-dominant trees included Quercus

rubra, and *Quercus macrocarpa*. The mid-size classes (6-10 inches DBH) were more diverse, and dominated by *Fraxinus americana*, *Tilia americana*, *Ulmus americana*, *Quercus ellipsoidalis*, and *Carya ovata*. Lower size classes (0-6 inches DBH) included shrubs and reproduction from the mid-size classes. Dominant trees undergoing reproduction included *Ulmus americana*, *Fraxinus americana*, and *Tilia americana*; also the oaks *Quercus ellipsoidalis*, and *Quercus rubra* occurred at low densities in lower size classes. The shrub layer is dominated by *Prunus virginiana*, *Prunus serotina*, *Ostrya virginiana*, and the introduced *Rhamnus cathartica*. Other important understory plants include the exotics *Rhamnus frangula*, and *Lonicera tatarica*.

WADSWORTH SAVANNA

Ground Cover

Quadrat sampling encountered 102 herbaceous, graminoid, or cyperoid plant species at Wadsworth Savanna. Dominant (Importance Value ≥ 2.0) (Table 11) herbaceous plants included *Smilacina racemosa*, *Trillium recurvatum*, *Geranium maculatum*, *Trillium grandiflorum*, *Sanicula gregaria*, *Taraxacum officinale*, and *Carex lacustris* (in wetlands). Dominant (IV ≥ 2.0) woody species under 1m included *Viburnum dentatum*, *Cornus racemosa*, *Rubus* sp., *Corylus americana*, *Lonicera tatarica*, *Rhamnus cathartica*, and *Viburnum prunifolium*. Fuel primarily was from leaf litter (Mean IV = 13.75) and graminoid/cyperoid cover (mean IV = 11.0), but wood litter also was abundant (Mean IV = 7.425).

Woody vegetation

Upper size classes (18-26 inches DBH) sampled at Wadsworth were dominated by *Quercus alba* and *Quercus rubra* (Table 12). Mid-size classes

(10-18 inches DBH) were represented by *Carya ovata*, *Quercus alba*, *Prunus serotina*, *Juglans cinerea*, *Populus grandidentata*, *Quercus ellipsoidalis*, and *Quercus palustris*. Lower size classes (0-10 inches DBH) contained more than 25 species. Dominant species included European buckthorns (*Rhamnus frangula* and *R. cathartica*), *Corylus americana*, *Cornus racemosa*, *Viburnum dentatum*, and *Lonicera tatarica*. Some minimal oak reproduction occurred from *Quercus ellipsoidalis* occurred.

SOMME PRAIRIE AND SAVANNA

Ground cover

Quadrat sampling encountered over 190 herbaceous grass, and sedge species at Somme Prairie and Savanna (Table 13). However, only one such species (*Geum canadense*) had an importance value over 2.0. Other dominant species included *Poa pratense*, *Carex laxiflora*, *Eragrostis virginianae*, and *Solidago juncea*. Dominant woody species under 1m included *Rhamnus cathartica*, *Cornus racemosa*, *Prunus serotina*, *Crataegus* sp., *Prunus virginiana*, and *Lonicera tatarica*. The Eurasian shrub *R. cathartica* had the highest relative frequency, relative cover, and important value of all species under 1 meter. Leaf litter and wood litter contributed almost equally to fuel with mean important values of 7.5 and 7.3, respectively; however, graminoid/cyperoid cover contributed more with a mean value of 13.2 per transect.

Woody Vegetation

Upper size class (18-26 inches DBH) sampled at Somme included only *Quercus macrocarpa*, but these trees were rare; control transects encountered only *Fraxinus americana* and *Quercus ellipsoidalis* in these size classes (Table 14). Mid-size-classes (10-18 inches DBH) were characterized by a

heterogeneous mixture including *Carya ovata*, *Populus alba* (Eurasian), *Robinia pseudoacacia*, *Prunus serotina*, *Fraxinus americana*, and *Quercus rubra*. Lower size classes were dominated by European buckthorn (*Rhamnus* sp.), *Crataegus* sp., dogwood (*Cornus racemosa*), and Eurasian honeysuckle (*Lonicera* sp.).

MIDDLEFORK SAVANNA

Ground Cover

Quadrat sampling encountered over 100 herbaceous, graminoid, or cyperoid species at Middlefork Savanna (Table 15). Dominant (highest importance values) examples of these species included *Carex pensylvanica* (IV = 3.80), *Andropogon gerardi* (IV = 3.79), *Eragrostis virginiana* (IV = 2.77), *Solidago juncea* (IV = 2.51), and *Helianthus divaricatus* (IV = 1.85). Other significant species include *Comandra richardsoniana* (IV = 1.42), *Dodecatheon meadia* (IV = 1.34), *Silphium terebinthinaceum*, *Cypripedium calceolus*, and the state-endangered *Platanthera leucophaea*. Important woody species encountered by quadrat sampling include *Cornus racemosa* (IV = 2.43), *Rhamnus cathartica* (IV = 2.43), *Rosa carolina* (IV = 1.84), *Lonicera tatarica* (IV = 1.29), and *Smilax herbacea* (IV = 1.25). Leaf litter and wood litter contributed equally to fuel (Mean IV/transect = 12); however graminoid/cyperoid cover contributed heavily with a mean value of 24.8 per transect.

Woody Vegetation

Upper size classes (18-26 inches DBH) were exclusively dominated by *Quercus alba* and *Quercus macrocarpa* (Table 16). Woody species almost totally were absent from the mid-size classes (6-18 inches DBH), while lower

size class (0-6 inches DBH) were dominated by *Coronis racemosa*, *Rhamnus cathartica*, *Quercus macrocarpa*, and *Quercus ellipsoidalis*.

DISCUSSION

REED-TURNER WOODLAND

At Reed-Turner Woodland, herbaceous species richness and natural quality appear directly related to overstory and understory woody canopy cover (Table 17). Herbaceous native species richness and mean natural quality index all were highest for the yard study area, which is free of canopy cover. In contrast, the east woods study area, which has a closed woody understory and tree canopy had lower species richness and natural quality but higher levels of woody plant cover, leaf litter, and woody litter. The center and west woods (a composite study area) was intermediate in species richness but low in species density. This large area is heterogeneous, with mixed areas of open and closed understory structure, but primarily it has a closed overstory structure. Summer- and fall-flowering savanna species, which are rare at Reed-Turner, are restricted to these opening or to open study areas.

Woody vegetation structure at Reed-Turner (Figure 7 & 8) appears characteristic of fire protected woodlands. Larger (older) size classes are dominated by white, red and bur oaks. However, these trees occur at relatively low densities in the mid-size classes where dominant trees are white ash and basswood. White oak is almost totally absent from the smallest size classes, except for reproduction encountered in the open yard study area. Instead, white ash, American elm, and basswood constitute the primary tree reproduction. In addition to native shrub species, the introduced buckthorns and tartarian honeysuckle are locally abundant in the forest understory.

These data support the argument that profound changes have taken place at Reed-Turner Woods Nature Preserve. These changes appear caused by shading and competition from a closed understory, presumably due to protection from fire, which promotes understory openings and maintains comparatively higher light levels. We suggest that disturbance by fire originally sustained a white, bur, and red oak-dominated woodland with a herbaceous and graminoid-rich fuel base. Fire protection has allowed reproduction by the more shade tolerant but fire sensitive white ash, basswood, and American elm. Shade from these woody species has restricted oak and graminoid reproduction to rare open patches and dramatically lowered species diversity and richness.

WADSWORTH SAVANNA

Herbaceous vegetation at Wadsworth was diverse, with over 100 herbs, grasses, or sedges encountered by sampling. Although canopy conditions now are relatively closed, few species characteristic of forest conditions were encountered and the most common species are more typical of open woodland; presumably, these species are remnants from more open savanna conditions.

As expected, woody tree species were not equally distributed through all size classes. Their distribution appears to represent a former oak-dominated community with reproduction and succession in smaller size classes now represented by shade tolerant canopy species and understory shrubs. Larger size classes contain only red and white oak, but the latter species was not present as reproduction in the smallest size class.

SOMME PRAIRIE AND SAVANNA

Although this site had extremely high species diversity, few were

conservative prairie or savanna species, and this diversity reflects a high heterogeneity of disturbed habitat with many Eurasian species. Although some herbaceous savanna species were present, they occurred at low frequencies (apparently due to intense past grazing) and contributed little to total importance value.

Woody understory species were dominated by the Eurasian Rhamnus cathartica. Mid-size classes include a diversity of species, but several (Populus alba and Robinia pseudacacia) reflect a long history of disturbance. Upper size classes contained few species. The presence of bur oak suggests a former savanna condition; but the presence of Fraxinus americana and Quercus ellipsoidalis in these upper size classes also suggests a relatively long history of disturbance.

MIDDLEFORK SAVANNA

Herbaceous vegetation at Middlefork Savanna was diverse, with over 100 species of grasses, sedges, and forbs encountered in only 450 meters of transects. Many of these were more conservative prairie and savanna species; while the characteristic prairie grass big bluestem was the second most important species encountered; very few species typical of more closed savanna conditions were present.

Woody vegetation was bimodally distributed by size-classes. Large bur and white oak formed a savanna overstory. However, trees were absent from mid-size classes, presumably due to a recent fire and moderate grazing history. Bur oak was well represented by reproduction in lower size classes and was co-dominant with dogwood and buckthorn, presumably in response to high light levels generated by past fire and moderate grazing.

TABLE 11. RELATION BETWEEN WOODY CANOPY COVER, SPECIES RICHNESS,
AND MEAN NATURAL QUALITY AT REED TURNER NATURE PRESERVE

	EAST WOODS	CENTER WOODS	YARD
CANOPY	CLOSED	CLOSED	OPEN
UNDERSTORY	CLOSED	MIXED	OPEN
RELATIVE IMPORTANCE VALUE			
WOODY PLANTS	33.75	16.00	17.75
LEAF LITTER	32.00	30.00	8.00
WOODY LITTER	10.75	11.25	5.50
SPECIES RICHNESS () = MEAN No. SPECIES/METER SQUARE			
TOTAL SPECIES	36 (6.65)	54 (6.41)	69 (14.25)
WOODY SPECIES	17 (2.5)	19 (1.07)	20 (2.625)
NON-WOODY SPECIES	19 (4.15)	35 (5.34)	49 (11.625)
NATURAL QUALITY INDEX (BURN/ NON-BURN)	7.0/7.4	6.8/8.0	9.4/12
No. OF QUADRATS	26	68	16
