DNR adequately protect workers and the general public? Elaboration: IDNR does not define a Fixed Date ( $\pm X$  days) for testing. Day 1, <Hour 1 test results will be orders of magnitude lower than either Day 2 or Day 10 tests results, and Day 10 tests results will be significantly lower than Day 80 ( $\pm 7$  days) results. Failure to specify a Fixed Test Date ( $\pm X$  days) renders test data so many irrelevant apples and oranges and allows companies to report suppressed, meaningless results by reporting Day 1, < 1 Hour data. The figure below, provided by the USGS, illustrates the nature of the problem. Please note that radium is not tested at Day 1, < 1 Hour. However, radium coprecipitates with barium, which is represented in total dissolved solids (TDS). It will therefore track TDS fairly closely. Conclusion: companies will be testing the very first flowback water to emerge from a fracked well. It will be Day 1, Minute 1 test results. 2.) There are two pits on a frack pad, one for "emergency" flowback and another, smaller one for drill cuttings and drilling mud. It is a basic principle in horizontal fracking to steer the drill bit through the horizontal strata with the highest gamma radiation readings (GAPI logs). The reason is that radioactivity correlates highly with total organic content (TOC) in the rock, and TOC correlates highly with oil and gas yields. This means that rock cuttings in the smaller drill mud and cuttings frack pit will often be more radioactive than flowback water. The IDNR knows this; yet it does not call for testing of drill bit pits as allowed under the Powers and duties section of the Act (§1- 15). 3.) The term "adjacent to" requires a "precise, clear standard" [IAPA, §100/5-20]. None is given. Does "adjacent to" mean 6 inches, 16 inches, 6 feet, 16 feet, or 60 feet? The IDNR does not say. 4.) Frack pad pipes and equipment can become incredibly radioactive over time. The very large temperature and pressure drops, as fluids move to the surface from thousands of feet underground, means that aqueous radioactive salts precipitate out as scale on pipes and equipment. The levels of radioactivity in pipe scale can exceed 100,000 picoCuries per gram and constitute a hazard to workers, or others who are exposed to recycled scrap metal from gas and oil operations. Yet, IDNR does not call on its General Assembly deferred "Power and authority" [Act, §1-15(e)] to test pipe, tanks, sludge, and equipment. This issue has been an issue in the oil and gas industry since the 1980s. Consequences: According to studies by the Illinois State Geological Survey, the Illinois New Albany Shale Formation, the source rock for our oil and gas reserves, has above average levels of uranium (29 ppm). Uranium decays into radium and thence radon. Both uranium and radium are water soluble. As noted, the U.S. Geological Survey has found oil field brine or produced water in Southern Illinois to have Radium226 levels that average more than 1,000 picoCuries / liter (USGS 1999). That reading is 67 times above the maximum contamination level of the EPA. Radium226 has a half life of 1,600 years. Uranium228 has a half life of 4.468 billion years. If these water soluble salts leach into our aquifers, nearby communities will require--if possible--very expensive water treatment for the next 1,000 years. We may have to return to rainwater harvesting with the modern equivalent of cisterns. The radioactive levels for produced water from shale gas operations are likely to be 2 to 4 times higher than oilfield brine -- on average, 2,000 to 4,000 picoCuries per liter. In addition, radon levels in methane, propane, and ethane can be dangerously high. When it becomes commercial to extract shale gas from the SE corner of the state, major markets, such as Springfield and Chicago, will only be 0.9 and 1.4 days removed from shale gas wellheads. Even though radon222 has a half life of only 3.8 days, the closeness of major Illinois retail gas markets will mean that large number of people will be breathing in high levels of radon when they cook meals. The average level of indoor exposure to radon in Illinois is already 4.4

## Fair Economy Illinois

---

pCi/L ( American Lung Association 2013). The EPA maximum level--the point at which corrective action should be taken--is 4.0 pCi/L, and the preferred level is =3.0 pCi/L. The turn to shale gas, with its high levels of radon, will also turn a major Illinois public health problem in the wrong direction. Radioactive scale in pipe and equipment presents another problem; high levels of radioactivity have been found in school playground equipment and bleachers in school sports stadiums in Mississippi and Texas. Do we want untested oil and gas field scrap metal sold into Illinois markets? Do we want our children exposed on a daily basis to radioactive metal? The present rules creates no barriers to such an outcome. The problems cited above are why Illinois, with its large number of nuclear power plants, has a Low-Level Radioactive Waste Management Act. It and OSHA are the applicable State and Federal agencies with respect to the issue of radioactive waste and work safety standards in settings with exposure to radioactivity. If we faithfully follow applicable State and federal laws, Illinois can minimize the pernicious problems other states are going to face from the uncontrolled release of radioactive elements into their water and soil and work and non-work settings. We should prevent these problem from the start. Cleanup, after the oil and gas industry is gone, will be dreadfully expensive.. Recommendations: 1. Define the test date as = Day 21, the point at which increases in test results begin to level off. 2. Test for "radioactivity" in (1) flowback/produced water, (2) drill cuttings, soil "adjacent to" (3) storage tanks and (4) reserve pits, and (5) pipes and well pad equipment. 3. Define "adjacent to" as between 6 and 12 inches with test samples to be taken within the top 6 inches of soil 4. The rules should also require that the requirements of the Illinois Low Level Radioactivity Waste Management Act be followed.

Sincerely, James Alstrum Normal, IL 61761

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Act §1-75(a)7 requires radioactivity testing "once per well site" for (1) flowback water and ground "adjacent to" (2) storage tanks and (3) reserve pits. Act § 1-120 requires IDNR compliance with all "applicable federal, State, and local laws." One applicable State law is the Illinois Low-Level Radioactive Waste Management Act (PA 83-991 / 420ILCS20). Another is the Occupational Health and Safety Administration (OSHA) standards for workplace safety in settings with exposure to radioactivity (29 CFR 1910.1096). Rules §245.850(d)1-E and §245.850(e) are incomplete and deficient, and these inadequacies can "constitute a serious threat"--indeed, deadly threat-- "to the public interest, safety, or welfare" of Illinois citizens." Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Notably absent from these proposed rules is a requirement for the testing of "produced water", the fluid that returns from the well during the later stage of production (after flowback). Under the proposed rules, "produced water" can be stored on site and/or can be "recycled", yet there is no testing requirement. Naturally occurring radioactive material (NORM) is found in "produced water" also. See Technologically enhanced naturally occurring radioactive materials in the oil industry (TENORM), Nukleonika 2009; 54(1):3-9, and sources cited therein, especially for TENORM in produced water in the U.S., available at [http://www.nukleonika.pl/www/back/full/vol54\\_2009/v54n1p003f.pdf](http://www.nukleonika.pl/www/back/full/vol54_2009/v54n1p003f.pdf). See also NORM is also found on scale in oil pipes and on fracking equipment. (See Kentucky Resources Council Proposes Comprehensive Plan For Investigating Radiological Contamination In Martha Oil Field. August 11, 2005. <http://www.kyrc.org/webnewspro/112381723236086.shtml>.) IDNR's definitions of "flowback water" and "produced water" are different. The two are distinguishably different enough that they are treated as separate types of fluid by both the Hydraulic Fracturing Regulatory Act and by the DNR Rules. Discharge of produced water onto the ground or into surface water or water drainage way is prohibited but it is not tested for radioactivity. This despite the fact that this fluid will be in contact with the naturally occurring radioactive elements in the ground for a longer period than the flowback and that it is much more likely to be radioactive. Problems: Failure to test produced water for radioactivity is problematic for a variety of reasons including: The health and safety of workers on the site who will be unaware of the levels of radioactivity they are being exposed to. The health and safety of workers transporting produced water who will also be in the dark regarding the levels of radioactivity they will be exposed to. The risk of storing radioactive material in tanks not created for storing radioactive materials. The risk of "recycling" produced water—radioactivity cannot be removed by recycling. The risk to the public in transporting radioactive materials Argonne National Laboratory recently cautioned about radiological doses: "It is commonly accepted that efforts should be undertaken at all times to keep radiological doses 'as low as reasonably achievable,' which is referred to as the ALARA principle or requirement." Overview of Radiological Dose and Risk Assessment (April 2011). DNR is failing to even adequately test for radioactivity and therefore, will not know the levels of radioactivity. How, then, can

DNR adequately protect workers and the general public? Elaboration: IDNR does not define a Fixed Date ( $\pm X$  days) for testing. Day 1, <Hour 1 test results will be orders of magnitude lower than either Day 2 or Day 10 tests results, and Day 10 tests results will be significantly lower than Day 80 ( $\pm 7$  days) results. Failure to specify a Fixed Test Date ( $\pm X$  days) renders test data so many irrelevant apples and oranges and allows companies to report suppressed, meaningless results by reporting Day 1, < 1 Hour data. The figure below, provided by the USGS, illustrates the nature of the problem. Please note that radium is not tested at Day 1, < 1 Hour. However, radium coprecipitates with barium, which is represented in total dissolved solids (TDS). It will therefore track TDS fairly closely. Conclusion: companies will be testing the very first flowback water to emerge from a fracked well. It will be Day 1, Minute 1 test results. 2.) There are two pits on a frack pad, one for "emergency" flowback and another, smaller one for drill cuttings and drilling mud. It is a basic principle in horizontal fracking to steer the drill bit through the horizontal strata with the highest gamma radiation readings (GAPI logs). The reason is that radioactivity correlates highly with total organic content (TOC) in the rock, and TOC correlates highly with oil and gas yields. This means that rock cuttings in the smaller drill mud and cuttings frack pit will often be more radioactive than flowback water. The IDNR knows this; yet it does not call for testing of drill bit pits as allowed under the Powers and duties section of the Act (§1- 15). 3.) The term "adjacent to" requires a "precise, clear standard" [IAPA, §100/5-20]. None is given. Does "adjacent to" mean 6 inches, 16 inches, 6 feet, 16 feet, or 60 feet? The IDNR does not say. 4.) Frack pad pipes and equipment can become incredibly radioactive over time. The very large temperature and pressure drops, as fluids move to the surface from thousands of feet underground, means that aqueous radioactive salts precipitate out as scale on pipes and equipment. The levels of radioactivity in pipe scale can exceed 100,000 picoCuries per gram and constitute a hazard to workers, or others who are exposed to recycled scrap metal from gas and oil operations. Yet, IDNR does not call on its General Assembly deferred "Power and authority" [Act, §1-15(e)] to test pipe, tanks, sludge, and equipment. This issue has been an issue in the oil and gas industry since the 1980s. Consequences: According to studies by the Illinois State Geological Survey, the Illinois New Albany Shale Formation, the source rock for our oil and gas reserves, has above average levels of uranium (29 ppm). Uranium decays into radium and thence radon. Both uranium and radium are water soluble. As noted, the U.S. Geological Survey has found oil field brine or produced water in Southern Illinois to have Radium226 levels that average more than 1,000 picoCuries / liter (USGS 1999). That reading is 67 times above the maximum contamination level of the EPA. Radium226 has a half life of 1,600 years. Uranium228 has a half life of 4.468 billion years. If these water soluble salts leach into our aquifers, nearby communities will require--if possible--very expensive water treatment for the next 1,000 years. We may have to return to rainwater harvesting with the modern equivalent of cisterns. The radioactive levels for produced water from shale gas operations are likely to be 2 to 4 times higher than oilfield brine -- on average, 2,000 to 4,000 picoCuries per liter. In addition, radon levels in methane, propane, and ethane can be dangerously high. When it becomes commercial to extract shale gas from the SE corner of the state, major markets, such as Springfield and Chicago, will only be 0.9 and 1.4 days removed from shale gas wellheads. Even though radon222 has a half life of only 3.8 days, the closeness of major Illinois retail gas markets will mean that large number of people will be breathing in high levels of radon when they cook meals. The average level of indoor exposure to radon in Illinois is already 4.4

## Fair Economy Illinois

---

pCi/L ( American Lung Association 2013). The EPA maximum level--the point at which corrective action should be taken--is 4.0 pCi/L, and the preferred level is =3.0 pCi/L. The turn to shale gas, with its high levels of radon, will also turn a major Illinois public health problem in the wrong direction. Radioactive scale in pipe and equipment presents another problem; high levels of radioactivity have been found in school playground equipment and bleachers in school sports stadiums in Mississippi and Texas. Do we want untested oil and gas field scrap metal sold into Illinois markets? Do we want our children exposed on a daily basis to radioactive metal? The present rules creates no barriers to such an outcome. The problems cited above are why Illinois, with its large number of nuclear power plants, has a Low-Level Radioactive Waste Management Act. It and OSHA are the applicable State and Federal agencies with respect to the issue of radioactive waste and work safety standards in settings with exposure to radioactivity. If we faithfully follow applicable State and federal laws, Illinois can minimize the pernicious problems other states are going to face from the uncontrolled release of radioactive elements into their water and soil and work and non-work settings. We should prevent these problem from the start. Cleanup, after the oil and gas industry is gone, will be dreadfully expensive.. Recommendations: 1. Define the test date as = Day 21, the point at which increases in test results begin to level off. 2. Test for "radioactivity" in (1) flowback/produced water, (2) drill cuttings, soil "adjacent to" (3) storage tanks and (4) reserve pits, and (5) pipes and well pad equipment. 3. Define "adjacent to" as between 6 and 12 inches with test samples to be taken within the top 6 inches of soil 4. The rules should also require that the requirements of the Illinois Low Level Radioactivity Waste Management Act be followed.

Sincerely, Jason Busser Dixon, IL 61021

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Act §1-75(a)7 requires radioactivity testing "once per well site" for (1) flowback water and ground "adjacent to" (2) storage tanks and (3) reserve pits. Act § 1-120 requires IDNR compliance with all "applicable federal, State, and local laws." One applicable State law is the Illinois Low-Level Radioactive Waste Management Act (PA 83-991 / 420ILCS20). Another is the Occupational Health and Safety Administration (OSHA) standards for workplace safety in settings with exposure to radioactivity (29 CFR 1910.1096). Rules §245.850(d)1-E and §245.850(e) are incomplete and deficient, and these inadequacies can "constitute a serious threat"--indeed, deadly threat-- "to the public interest, safety, or welfare" of Illinois citizens." Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Notably absent from these proposed rules is a requirement for the testing of "produced water", the fluid that returns from the well during the later stage of production (after flowback). Under the proposed rules, "produced water" can be stored on site and/or can be "recycled", yet there is no testing requirement. Naturally occurring radioactive material (NORM) is found in "produced water" also. See Technologically enhanced naturally occurring radioactive materials in the oil industry (TENORM), Nukleonika 2009; 54(1):3-9, and sources cited therein, especially for TENORM in produced water in the U.S., available at [http://www.nukleonika.pl/www/back/full/vol54\\_2009/v54n1p003f.pdf](http://www.nukleonika.pl/www/back/full/vol54_2009/v54n1p003f.pdf). See also NORM is also found on scale in oil pipes and on fracking equipment. (See Kentucky Resources Council Proposes Comprehensive Plan For Investigating Radiological Contamination In Martha Oil Field. August 11, 2005. <http://www.kyrc.org/webnewspro/112381723236086.shtml>.) IDNR's definitions of "flowback water" and "produced water" are different. The two are distinguishably different enough that they are treated as separate types of fluid by both the Hydraulic Fracturing Regulatory Act and by the DNR Rules. Discharge of produced water onto the ground or into surface water or water drainage way is prohibited but it is not tested for radioactivity. This despite the fact that this fluid will be in contact with the naturally occurring radioactive elements in the ground for a longer period than the flowback and that it is much more likely to be radioactive. Problems: Failure to test produced water for radioactivity is problematic for a variety of reasons including: The health and safety of workers on the site who will be unaware of the levels of radioactivity they are being exposed to. The health and safety of workers transporting produced water who will also be in the dark regarding the levels of radioactivity they will be exposed to. The risk of storing radioactive material in tanks not created for storing radioactive materials. The risk of "recycling" produced water—radioactivity cannot be removed by recycling. The risk to the public in transporting radioactive materials Argonne National Laboratory recently cautioned about radiological doses: "It is commonly accepted that efforts should be undertaken at all times to keep radiological doses 'as low as reasonably achievable,' which is referred to as the ALARA principle or requirement." Overview of Radiological Dose and Risk Assessment (April 2011). DNR is failing to even adequately test for radioactivity and therefore, will not know the levels of radioactivity. How, then, can

## Fair Economy Illinois

---

DNR adequately protect workers and the general public? Elaboration: IDNR does not define a Fixed Date ( $\pm X$  days) for testing. Day 1, <Hour 1 test results will be orders of magnitude lower than either Day 2 or Day 10 tests results, and Day 10 tests results will be significantly lower than Day 80 ( $\pm 7$  days) results. Failure to specify a Fixed Test Date ( $\pm X$  days) renders test data so many irrelevant apples and oranges and allows companies to report suppressed, meaningless results by reporting Day 1, < 1 Hour data. The figure below, provided by the USGS, illustrates the nature of the problem. Please note that radium is not tested at Day 1, < 1 Hour. However, radium coprecipitates with barium, which is represented in total dissolved solids (TDS). It will therefore track TDS fairly closely. Conclusion: companies will be testing the very first flowback water to emerge from a fracked well. It will be Day 1, Minute 1 test results. 2.) There are two pits on a frack pad, one for "emergency" flowback and another, smaller one for drill cuttings and drilling mud. It is a basic principle in horizontal fracking to steer the drill bit through the horizontal strata with the highest gamma radiation readings (GAPI logs). The reason is that radioactivity correlates highly with total organic content (TOC) in the rock, and TOC correlates highly with oil and gas yields. This means that rock cuttings in the smaller drill mud and cuttings frack pit will often be more radioactive than flowback water. The IDNR knows this; yet it does not call for testing of drill bit pits as allowed under the Powers and duties section of the Act (§1- 15). 3.) The term "adjacent to" requires a "precise, clear standard" [IAPA, §100/5-20]. None is given. Does "adjacent to" mean 6 inches, 16 inches, 6 feet, 16 feet, or 60 feet? The IDNR does not say. 4.) Frack pad pipes and equipment can become incredibly radioactive over time. The very large temperature and pressure drops, as fluids move to the surface from thousands of feet underground, means that aqueous radioactive salts precipitate out as scale on pipes and equipment. The levels of radioactivity in pipe scale can exceed 100,000 picoCuries per gram and constitute a hazard to workers, or others who are exposed to recycled scrap metal from gas and oil operations. Yet, IDNR does not call on its General Assembly deferred "Power and authority" [Act, §1-15(e)] to test pipe, tanks, sludge, and equipment. This issue has been an issue in the oil and gas industry since the 1980s. Consequences: According to studies by the Illinois State Geological Survey, the Illinois New Albany Shale Formation, the source rock for our oil and gas reserves, has above average levels of uranium (29 ppm). Uranium decays into radium and thence radon. Both uranium and radium are water soluble. As noted, the U.S. Geological Survey has found oil field brine or produced water in Southern Illinois to have Radium226 levels that average more than 1,000 picoCuries / liter (USGS 1999). That reading is 67 times above the maximum contamination level of the EPA. Radium226 has a half life of 1,600 years. Uranium228 has a half life of 4.468 billion years. In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Act §1-75(a)7 requires radioactivity testing "once per well site" for (1) flowback water and ground "adjacent to" (2) storage tanks and (3) reserve pits. Act § 1-120 requires IDNR compliance with all "applicable federal, State, and local laws." One applicable State law is the Illinois Low-Level Radioactive Waste Management Act (PA 83-991 / 420ILCS20). Another is the Occupational Health and Safety Administration (OSHA) standards for workplace safety in settings with exposure to radioactivity (29 CFR 1910.1096). Rules §245.850(d)1-E and §245.850(e) are incomplete and deficient, and these inadequacies can "constitute a serious threat"--indeed, deadly threat-- "to the public interest, safety, or welfare" of Illinois citizens." Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Notably absent from these proposed rules is a requirement for the testing of "produced water", the fluid that returns from the well during the later stage of production (after flowback). Under the proposed rules, "produced water" can be stored on site and/or can be "recycled", yet there is no testing requirement. Naturally occurring radioactive material (NORM) is found in "produced water" also. See Technologically enhanced naturally occurring radioactive materials in the oil industry (TENORM), Nukleonika 2009; 54(1):3-9, and sources cited therein, especially for TENORM in produced water in the U.S., available at [http://www.nukleonika.pl/www/back/full/vol54\\_2009/v54n1p003f.pdf](http://www.nukleonika.pl/www/back/full/vol54_2009/v54n1p003f.pdf). See also NORM is also found on scale in oil pipes and on fracking equipment. (See Kentucky Resources Council Proposes Comprehensive Plan For Investigating Radiological Contamination In Martha Oil Field. August 11, 2005. <http://www.kyrc.org/webnewspro/112381723236086.shtml>.) IDNR's definitions of "flowback water" and "produced water" are different. The two are distinguishably different enough that they are treated as separate types of fluid by both the Hydraulic Fracturing Regulatory Act and by the DNR Rules. Discharge of produced water onto the ground or into surface water or water drainage way is prohibited but it is not tested for radioactivity. This despite the fact that this fluid will be in contact with the naturally occurring radioactive elements in the ground for a longer period than the flowback and that it is much more likely to be radioactive. Problems: Failure to test produced water for radioactivity is problematic for a variety of reasons including: The health and safety of workers on the site who will be unaware of the levels of radioactivity they are being exposed to. The health and safety of workers transporting produced water who will also be in the dark regarding the levels of radioactivity they will be exposed to. The risk of storing radioactive material in tanks not created for storing radioactive materials. The risk of "recycling" produced water—radioactivity cannot be removed by recycling. The risk to the public in transporting radioactive materials Argonne National Laboratory recently cautioned about radiological doses: "It is commonly accepted that efforts should be undertaken at all times to keep radiological doses 'as low as reasonably achievable,' which is referred to as the ALARA principle or requirement." Overview of Radiological Dose and Risk Assessment (April 2011). DNR is failing to even adequately test for radioactivity and therefore, will not know the levels of radioactivity. How, then, can

## Fair Economy Illinois

---

DNR adequately protect workers and the general public? Elaboration: IDNR does not define a Fixed Date ( $\pm X$  days) for testing. Day 1, <Hour 1 test results will be orders of magnitude lower than either Day 2 or Day 10 tests results, and Day 10 tests results will be significantly lower than Day 80 ( $\pm 7$  days) results. Failure to specify a Fixed Test Date ( $\pm X$  days) renders test data so many irrelevant apples and oranges and allows companies to report suppressed, meaningless results by reporting Day 1, < 1 Hour data. The figure below, provided by the USGS, illustrates the nature of the problem. Please note that radium is not tested at Day 1, < 1 Hour. However, radium coprecipitates with barium, which is represented in total dissolved solids (TDS). It will therefore track TDS fairly closely. Conclusion: companies will be testing the very first flowback water to emerge from a fracked well. It will be Day 1, Minute 1 test results. 2.) There are two pits on a frack pad, one for "emergency" flowback and another, smaller one for drill cuttings and drilling mud. It is a basic principle in horizontal fracking to steer the drill bit through the horizontal strata with the highest gamma radiation readings (GAPI logs). The reason is that radioactivity correlates highly with total organic content (TOC) in the rock, and TOC correlates highly with oil and gas yields. This means that rock cuttings in the smaller drill mud and cuttings frack pit will often be more radioactive than flowback water. The IDNR knows this; yet it does not call for testing of drill bit pits as allowed under the Powers and duties section of the Act (§1- 15). 3.) The term "adjacent to" requires a "precise, clear standard" [IAPA, §100/5-20]. None is given. Does "adjacent to" mean 6 inches, 16 inches, 6 feet, 16 feet, or 60 feet? The IDNR does not say. 4.) Frack pad pipes and equipment can become incredibly radioactive over time. The very large temperature and pressure drops, as fluids move to the surface from thousands of feet underground, means that aqueous radioactive salts precipitate out as scale on pipes and equipment. The levels of radioactivity in pipe scale can exceed 100,000 picoCuries per gram and constitute a hazard to workers, or others who are exposed to recycled scrap metal from gas and oil operations. Yet, IDNR does not call on its General Assembly deferred "Power and authority" [Act, §1-15(e)] to test pipe, tanks, sludge, and equipment. This issue has been an issue in the oil and gas industry since the 1980s. Consequences: According to studies by the Illinois State Geological Survey, the Illinois New Albany Shale Formation, the source rock for our oil and gas reserves, has above average levels of uranium (29 ppm). Uranium decays into radium and thence radon. Both uranium and radium are water soluble. As noted, the U.S. Geological Survey has found oil field brine or produced water in Southern Illinois to have Radium226 levels that average more than 1,000 picoCuries / liter (USGS 1999). That reading is 67 times above the maximum contamination level of the EPA. Radium226 has a half life of 1,600 years. Uranium228 has a half life of 4.468 billion years. If these water soluble salts leach into our aquifers, nearby communities will require--if possible--very expensive water treatment for the next 1,000 years. We may have to return to rainwater harvesting with the modern equivalent of cisterns. The radioactive levels for produced water from shale gas operations are likely to be 2 to 4 times higher than oilfield brine -- on average, 2,000 to 4,000 picoCuries per liter. In addition, radon levels in methane, propane, and ethane can be dangerously high. When it becomes commercial to extract shale gas from the SE corner of the state, major markets, such as Springfield and Chicago, will only be 0.9 and 1.4 days removed from shale gas wellheads. Even though radon222 has a half life of only 3.8 days, the closeness of major Illinois retail gas markets will mean that large number of people will be breathing in high levels of radon when they cook meals. The average level of indoor exposure to radon in Illinois is already 4.4

## Fair Economy Illinois

---

pCi/L ( American Lung Association 2013). The EPA maximum level--the point at which corrective action should be taken--is 4.0 pCi/L, and the preferred level is =3.0 pCi/L. The turn to shale gas, with its high levels of radon, will also turn a major Illinois public health problem in the wrong direction. Radioactive scale in pipe and equipment presents another problem; high levels of radioactivity have been found in school playground equipment and bleachers in school sports stadiums in Mississippi and Texas. Do we want untested oil and gas field scrap metal sold into Illinois markets? Do we want our children exposed on a daily basis to radioactive metal? The present rules creates no barriers to such an outcome. The problems cited above are why Illinois, with its large number of nuclear power plants, has a Low-Level Radioactive Waste Management Act. It and OSHA are the applicable State and Federal agencies with respect to the issue of radioactive waste and work safety standards in settings with exposure to radioactivity. If we faithfully follow applicable State and federal laws, Illinois can minimize the pernicious problems other states are going to face from the uncontrolled release of radioactive elements into their water and soil and work and non-work settings. We should prevent these problem from the start. Cleanup, after the oil and gas industry is gone, will be dreadfully expensive.. Recommendations: 1. Define the test date as = Day 21, the point at which increases in test results begin to level off. 2. Test for "radioactivity" in (1) flowback/produced water, (2) drill cuttings, soil "adjacent to" (3) storage tanks and (4) reserve pits, and (5) pipes and well pad equipment. 3. Define "adjacent to" as between 6 and 12 inches with test samples to be taken within the top 6 inches of soil 4. The rules should also require that the requirements of the Illinois Low Level Radioactivity Waste Management Act be followed.

Sincerely, Jesse Silliman Chicago, IL 60615

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Act §1-75(a)7 requires radioactivity testing "once per well site" for (1) flowback water and ground "adjacent to" (2) storage tanks and (3) reserve pits. Act § 1-120 requires IDNR compliance with all "applicable federal, State, and local laws." One applicable State law is the Illinois Low-Level Radioactive Waste Management Act (PA 83-991 / 420ILCS20). Another is the Occupational Health and Safety Administration (OSHA) standards for workplace safety in settings with exposure to radioactivity (29 CFR 1910.1096). Rules §245.850(d)1-E and §245.850(e) are incomplete and deficient, and these inadequacies can "constitute a serious threat"--indeed, deadly threat-- "to the public interest, safety, or welfare" of Illinois citizens." Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Notably absent from these proposed rules is a requirement for the testing of "produced water", the fluid that returns from the well during the later stage of production (after flowback). Under the proposed rules, "produced water" can be stored on site and/or can be "recycled", yet there is no testing requirement. Naturally occurring radioactive material (NORM) is found in "produced water" also. See Technologically enhanced naturally occurring radioactive materials in the oil industry (TENORM), Nukleonika 2009; 54(1):3-9, and sources cited therein, especially for TENORM in produced water in the U.S., available at [http://www.nukleonika.pl/www/back/full/vol54\\_2009/v54n1p003f.pdf](http://www.nukleonika.pl/www/back/full/vol54_2009/v54n1p003f.pdf). See also NORM is also found on scale in oil pipes and on fracking equipment. (See Kentucky Resources Council Proposes Comprehensive Plan For Investigating Radiological Contamination In Martha Oil Field. August 11, 2005. <http://www.kyrc.org/webnewspro/112381723236086.shtml>.) IDNR's definitions of "flowback water" and "produced water" are different. The two are distinguishably different enough that they are treated as separate types of fluid by both the Hydraulic Fracturing Regulatory Act and by the DNR Rules. Discharge of produced water onto the ground or into surface water or water drainage way is prohibited but it is not tested for radioactivity. This despite the fact that this fluid will be in contact with the naturally occurring radioactive elements in the ground for a longer period than the flowback and that it is much more likely to be radioactive. Problems: Failure to test produced water for radioactivity is problematic for a variety of reasons including: The health and safety of workers on the site who will be unaware of the levels of radioactivity they are being exposed to. The health and safety of workers transporting produced water who will also be in the dark regarding the levels of radioactivity they will be exposed to. The risk of storing radioactive material in tanks not created for storing radioactive materials. The risk of "recycling" produced water—radioactivity cannot be removed by recycling. The risk to the public in transporting radioactive materials Argonne National Laboratory recently cautioned about radiological doses: "It is commonly accepted that efforts should be undertaken at all times to keep radiological doses 'as low as reasonably achievable,' which is referred to as the ALARA principle or requirement." Overview of Radiological Dose and Risk Assessment (April 2011). DNR is failing to even adequately test for radioactivity and therefore, will not know the levels of radioactivity. How, then, can

DNR adequately protect workers and the general public? Elaboration: IDNR does not define a Fixed Date ( $\pm X$  days) for testing. Day 1, <Hour 1 test results will be orders of magnitude lower than either Day 2 or Day 10 tests results, and Day 10 tests results will be significantly lower than Day 80 ( $\pm 7$  days) results. Failure to specify a Fixed Test Date ( $\pm X$  days) renders test data so many irrelevant apples and oranges and allows companies to report suppressed, meaningless results by reporting Day 1, < 1 Hour data. The figure below, provided by the USGS, illustrates the nature of the problem. Please note that radium is not tested at Day 1, < 1 Hour. However, radium coprecipitates with barium, which is represented in total dissolved solids (TDS). It will therefore track TDS fairly closely. Conclusion: companies will be testing the very first flowback water to emerge from a fracked well. It will be Day 1, Minute 1 test results. 2.) There are two pits on a frack pad, one for "emergency" flowback and another, smaller one for drill cuttings and drilling mud. It is a basic principle in horizontal fracking to steer the drill bit through the horizontal strata with the highest gamma radiation readings (GAPI logs). The reason is that radioactivity correlates highly with total organic content (TOC) in the rock, and TOC correlates highly with oil and gas yields. This means that rock cuttings in the smaller drill mud and cuttings frack pit will often be more radioactive than flowback water. The IDNR knows this; yet it does not call for testing of drill bit pits as allowed under the Powers and duties section of the Act (§1- 15). 3.) The term "adjacent to" requires a "precise, clear standard" [IAPA, §100/5-20]. None is given. Does "adjacent to" mean 6 inches, 16 inches, 6 feet, 16 feet, or 60 feet? The IDNR does not say. 4.) Frack pad pipes and equipment can become incredibly radioactive over time. The very large temperature and pressure drops, as fluids move to the surface from thousands of feet underground, means that aqueous radioactive salts precipitate out as scale on pipes and equipment. The levels of radioactivity in pipe scale can exceed 100,000 picoCuries per gram and constitute a hazard to workers, or others who are exposed to recycled scrap metal from gas and oil operations. Yet, IDNR does not call on its General Assembly deferred "Power and authority" [Act, §1-15(e)] to test pipe, tanks, sludge, and equipment. This issue has been an issue in the oil and gas industry since the 1980s. Consequences: According to studies by the Illinois State Geological Survey, the Illinois New Albany Shale Formation, the source rock for our oil and gas reserves, has above average levels of uranium (29 ppm). Uranium decays into radium and thence radon. Both uranium and radium are water soluble. As noted, the U.S. Geological Survey has found oil field brine or produced water in Southern Illinois to have Radium226 levels that average more than 1,000 picoCuries / liter (USGS 1999). That reading is 67 times above the maximum contamination level of the EPA. Radium226 has a half life of 1,600 years. Uranium228 has a half life of 4.468 billion years. If these water soluble salts leach into our aquifers, nearby communities will require--if possible--very expensive water treatment for the next 1,000 years. We may have to return to rainwater harvesting with the modern equivalent of cisterns. The radioactive levels for produced water from shale gas operations are likely to be 2 to 4 times higher than oilfield brine -- on average, 2,000 to 4,000 picoCuries per liter. In addition, radon levels in methane, propane, and ethane can be dangerously high. When it becomes commercial to extract shale gas from the SE corner of the state, major markets, such as Springfield and Chicago, will only be 0.9 and 1.4 days removed from shale gas wellheads. Even though radon222 has a half life of only 3.8 days, the closeness of major Illinois retail gas markets will mean that large number of people will be breathing in high levels of radon when they cook meals. The average level of indoor exposure to radon in Illinois is already 4.4

## Fair Economy Illinois

---

pCi/L ( American Lung Association 2013). The EPA maximum level--the point at which corrective action should be taken--is 4.0 pCi/L, and the preferred level is =3.0 pCi/L. The turn to shale gas, with its high levels of radon, will also turn a major Illinois public health problem in the wrong direction. Radioactive scale in pipe and equipment presents another problem; high levels of radioactivity have been found in school playground equipment and bleachers in school sports stadiums in Mississippi and Texas. Do we want untested oil and gas field scrap metal sold into Illinois markets? Do we want our children exposed on a daily basis to radioactive metal? The present rules creates no barriers to such an outcome. The problems cited above are why Illinois, with its large number of nuclear power plants, has a Low-Level Radioactive Waste Management Act. It and OSHA are the applicable State and Federal agencies with respect to the issue of radioactive waste and work safety standards in settings with exposure to radioactivity. If we faithfully follow applicable State and federal laws, Illinois can minimize the pernicious problems other states are going to face from the uncontrolled release of radioactive elements into their water and soil and work and non-work settings. We should prevent these problem from the start. Cleanup, after the oil and gas industry is gone, will be dreadfully expensive.. Recommendations: 1. Define the test date as = Day 21, the point at which increases in test results begin to level off. 2. Test for "radioactivity" in (1) flowback/produced water, (2) drill cuttings, soil "adjacent to" (3) storage tanks and (4) reserve pits, and (5) pipes and well pad equipment. 3. Define "adjacent to" as between 6 and 12 inches with test samples to be taken within the top 6 inches of soil 4. The rules should also require that the requirements of the Illinois Low Level Radioactivity Waste Management Act be followed.

Sincerely, Joe Kapran Chicago, IL 60615

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Act §1-75(a)7 requires radioactivity testing "once per well site" for (1) flowback water and ground "adjacent to" (2) storage tanks and (3) reserve pits. Act § 1-120 requires IDNR compliance with all "applicable federal, State, and local laws." One applicable State law is the Illinois Low-Level Radioactive Waste Management Act (PA 83-991 / 420ILCS20). Another is the Occupational Health and Safety Administration (OSHA) standards for workplace safety in settings with exposure to radioactivity (29 CFR 1910.1096). Rules §245.850(d)1-E and §245.850(e) are incomplete and deficient, and these inadequacies can "constitute a serious threat"--indeed, deadly threat-- "to the public interest, safety, or welfare" of Illinois citizens." Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Notably absent from these proposed rules is a requirement for the testing of "produced water", the fluid that returns from the well during the later stage of production (after flowback). Under the proposed rules, "produced water" can be stored on site and/or can be "recycled", yet there is no testing requirement. Naturally occurring radioactive material (NORM) is found in "produced water" also. See Technologically enhanced naturally occurring radioactive materials in the oil industry (TENORM), Nukleonika 2009; 54(1):3-9, and sources cited therein, especially for TENORM in produced water in the U.S., available at [http://www.nukleonika.pl/www/back/full/vol54\\_2009/v54n1p003f.pdf](http://www.nukleonika.pl/www/back/full/vol54_2009/v54n1p003f.pdf). See also NORM is also found on scale in oil pipes and on fracking equipment. (See Kentucky Resources Council Proposes Comprehensive Plan For Investigating Radiological Contamination In Martha Oil Field. August 11, 2005. <http://www.kyrc.org/webnewspro/112381723236086.shtml>.) IDNR's definitions of "flowback water" and "produced water" are different. The two are distinguishably different enough that they are treated as separate types of fluid by both the Hydraulic Fracturing Regulatory Act and by the DNR Rules. Discharge of produced water onto the ground or into surface water or water drainage way is prohibited but it is not tested for radioactivity. This despite the fact that this fluid will be in contact with the naturally occurring radioactive elements in the ground for a longer period than the flowback and that it is much more likely to be radioactive. Problems: Failure to test produced water for radioactivity is problematic for a variety of reasons including: The health and safety of workers on the site who will be unaware of the levels of radioactivity they are being exposed to. The health and safety of workers transporting produced water who will also be in the dark regarding the levels of radioactivity they will be exposed to. The risk of storing radioactive material in tanks not created for storing radioactive materials. The risk of "recycling" produced water—radioactivity cannot be removed by recycling. The risk to the public in transporting radioactive materials Argonne National Laboratory recently cautioned about radiological doses: "It is commonly accepted that efforts should be undertaken at all times to keep radiological doses 'as low as reasonably achievable,' which is referred to as the ALARA principle or requirement." In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Act §1-75(a)7 requires radioactivity testing "once per well site" for (1) flowback water and ground "adjacent to" (2) storage tanks and (3) reserve pits. Act § 1-120 requires IDNR compliance with all "applicable federal, State, and local laws." One applicable State law is the Illinois Low-Level Radioactive Waste Management Act (PA 83-991 / 420ILCS20). Another is the Occupational Health and Safety Administration (OSHA) standards for workplace safety in settings with exposure to radioactivity (29 CFR 1910.1096). Rules §245.850(d)1-E and §245.850(e) are incomplete and deficient, and these inadequacies can "constitute a serious threat"--indeed, deadly threat-- "to the public interest, safety, or welfare" of Illinois citizens." Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Notably absent from these proposed rules is a requirement for the testing of "produced water", the fluid that returns from the well during the later stage of production (after flowback). Under the proposed rules, "produced water" can be stored on site and/or can be "recycled", yet there is no testing requirement. Naturally occurring radioactive material (NORM) is found in "produced water" also. See Technologically enhanced naturally occurring radioactive materials in the oil industry (TENORM), Nukleonika 2009; 54(1):3-9, and sources cited therein, especially for TENORM in produced water in the U.S., available at [http://www.nukleonika.pl/www/back/full/vol54\\_2009/v54n1p003f.pdf](http://www.nukleonika.pl/www/back/full/vol54_2009/v54n1p003f.pdf). See also NORM is also found on scale in oil pipes and on fracking equipment. (See Kentucky Resources Council Proposes Comprehensive Plan For Investigating Radiological Contamination In Martha Oil Field. August 11, 2005. <http://www.kyrc.org/webnewspro/112381723236086.shtml>.) IDNR's definitions of "flowback water" and "produced water" are different. The two are distinguishably different enough that they are treated as separate types of fluid by both the Hydraulic Fracturing Regulatory Act and by the DNR Rules. Discharge of produced water onto the ground or into surface water or water drainage way is prohibited but it is not tested for radioactivity. This despite the fact that this fluid will be in contact with the naturally occurring radioactive elements in the ground for a longer period than the flowback and that it is much more likely to be radioactive. Problems: Failure to test produced water for radioactivity is problematic for a variety of reasons including: The health and safety of workers on the site who will be unaware of the levels of radioactivity they are being exposed to. The health and safety of workers transporting produced water who will also be in the dark regarding the levels of radioactivity they will be exposed to. The risk of storing radioactive material in tanks not created for storing radioactive materials. The risk of "recycling" produced water—radioactivity cannot be removed by recycling. The risk to the public in transporting radioactive materials Argonne National Laboratory recently cautioned about radiological doses: "It is commonly accepted that efforts should be undertaken at all times to keep radiological doses 'as low as reasonably achievable,' which is referred to as the ALARA principle or requirement." Overview of Radiological Dose and Risk Assessment (April 2011). DNR is failing to even adequately test for radioactivity and therefore, will not know the levels of radioactivity. How, then, can

## Fair Economy Illinois

---

DNR adequately protect workers and the general public? Elaboration: IDNR does not define a Fixed Date ( $\pm X$  days) for testing. Day 1, <Hour 1 test results will be orders of magnitude lower than either Day 2 or Day 10 tests results, and Day 10 tests results will be significantly lower than Day 80 ( $\pm 7$  days) results. Failure to specify a Fixed Test Date ( $\pm X$  days) renders test data so many irrelevant apples and oranges and allows companies to report suppressed, meaningless results by reporting Day 1, < 1 Hour data. The figure below, provided by the USGS, illustrates the nature of the problem. Please note that radium is not tested at Day 1, < 1 Hour. However, radium coprecipitates with barium, which is represented in total dissolved solids (TDS). It will therefore track TDS fairly closely. Conclusion: companies will be testing the very first flowback water to emerge from a fracked well. It will be Day 1, Minute 1 test results. 2.) There are two pits on a frack pad, one for "emergency" flowback and another, smaller one for drill cuttings and drilling mud. It is a basic principle in horizontal fracking to steer the drill bit through the horizontal strata with the highest gamma radiation readings (GAPI logs). The reason is that radioactivity correlates highly with total organic content (TOC) in the rock, and TOC correlates highly with oil and gas yields. This means that rock cuttings in the smaller drill mud and cuttings frack pit will often be more radioactive than flowback water. The IDNR knows this; yet it does not call for testing of drill bit pits as allowed under the Powers and duties section of the Act (§1- 15). 3.) The term "adjacent to" requires a "precise, clear standard" [IAPA, §100/5-20]. None is given. Does "adjacent to" mean 6 inches, 16 inches, 6 feet, 16 feet, or 60 feet? The IDNR does not say. 4.) Frack pad pipes and equipment can become incredibly radioactive over time. The very large temperature and pressure drops, as fluids move to the surface from thousands of feet underground, means that aqueous radioactive salts precipitate out as scale on pipes and equipment. The levels of radioactivity in pipe scale can exceed 100,000 picoCuries per gram and constitute a hazard to workers, or others who are exposed to recycled scrap metal from gas and oil operations. Yet, IDNR does not call on its General Assembly deferred "Power and authority" [Act, §1-15(e)] to test pipe, tanks, sludge, and equipment. This issue has been an issue in the oil and gas industry since the 1980s. Consequences: According to studies by the Illinois State Geological Survey, the Illinois New Albany Shale Formation, the source rock for our oil and gas reserves, has above average levels of uranium (29 ppm). Uranium decays into radium and thence radon. Both uranium and radium are water soluble. As noted, the U.S. Geological Survey has found oil field brine or produced water in Southern Illinois to have Radium226 levels that average more than 1,000 picoCuries / liter (USGS 1999). That reading is 67 times above the maximum contamination level of the EPA. Radium226 has a half life of 1,600 years. Uranium228 has a half life of 4.468 billion years. If these water soluble salts leach into our aquifers, nearby communities will require--if possible--very expensive water treatment for the next 1,000 years. We may have to return to rainwater harvesting with the modern equivalent of cisterns. The radioactive levels for produced water from shale gas operations are likely to be 2 to 4 times higher than oilfield brine -- on average, 2,000 to 4,000 picoCuries per liter. In addition, radon levels in methane, propane, and ethane can be dangerously high. When it becomes commercial to extract shale gas from the SE corner of the state, major markets, such as Springfield and Chicago, will only be 0.9 and 1.4 days removed from shale gas wellheads. Even though radon222 has a half life of only 3.8 days, the closeness of major Illinois retail gas markets will mean that large number of people will be breathing in high levels of radon when they cook meals. The average level of indoor exposure to radon in Illinois is already 4.4

## Fair Economy Illinois

---

pCi/L ( American Lung Association 2013). The EPA maximum level--the point at which corrective action should be taken--is 4.0 pCi/L, and the preferred level is =3.0 pCi/L. The turn to shale gas, with its high levels of radon, will also turn a major Illinois public health problem in the wrong direction. Radioactive scale in pipe and equipment presents another problem; high levels of radioactivity have been found in school playground equipment and bleachers in school sports stadiums in Mississippi and Texas. Do we want untested oil and gas field scrap metal sold into Illinois markets? Do we want our children exposed on a daily basis to radioactive metal? The present rules creates no barriers to such an outcome. The problems cited above are why Illinois, with its large number of nuclear power plants, has a Low-Level Radioactive Waste Management Act. It and OSHA are the applicable State and Federal agencies with respect to the issue of radioactive waste and work safety standards in settings with exposure to radioactivity. If we faithfully follow applicable State and federal laws, Illinois can minimize the pernicious problems other states are going to face from the uncontrolled release of radioactive elements into their water and soil and work and non-work settings. We should prevent these problem from the start. Cleanup, after the oil and gas industry is gone, will be dreadfully expensive.. Recommendations: 1. Define the test date as = Day 21, the point at which increases in test results begin to level off. 2. Test for "radioactivity" in (1) flowback/produced water, (2) drill cuttings, soil "adjacent to" (3) storage tanks and (4) reserve pits, and (5) pipes and well pad equipment. 3. Define "adjacent to" as between 6 and 12 inches with test samples to be taken within the top 6 inches of soil 4. The rules should also require that the requirements of the Illinois Low Level Radioactivity Waste Management Act be followed.

Sincerely, Johh Haggerty NYC, IL 11215

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Act §1-75(a)7 requires radioactivity testing "once per well site" for (1) flowback water and ground "adjacent to" (2) storage tanks and (3) reserve pits. Act § 1-120 requires IDNR compliance with all "applicable federal, State, and local laws." One applicable State law is the Illinois Low-Level Radioactive Waste Management Act (PA 83-991 / 420ILCS20). Another is the Occupational Health and Safety Administration (OSHA) standards for workplace safety in settings with exposure to radioactivity (29 CFR 1910.1096). Rules §245.850(d)1-E and §245.850(e) are incomplete and deficient, and these inadequacies can "constitute a serious threat"--indeed, deadly threat-- "to the public interest, safety, or welfare" of Illinois citizens." Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Notably absent from these proposed rules is a requirement for the testing of "produced water", the fluid that returns from the well during the later stage of production (after flowback). Under the proposed rules, "produced water" can be stored on site and/or can be "recycled", yet there is no testing requirement. Naturally occurring radioactive material (NORM) is found in "produced water" also. See Technologically enhanced naturally occurring radioactive materials in the oil industry (TENORM), Nukleonika 2009; 54(1):3-9, and sources cited therein, especially for TENORM in produced water in the U.S., available at [http://www.nukleonika.pl/www/back/full/vol54\\_2009/v54n1p003f.pdf](http://www.nukleonika.pl/www/back/full/vol54_2009/v54n1p003f.pdf). See also NORM is also found on scale in oil pipes and on fracking equipment. (See Kentucky Resources Council Proposes Comprehensive Plan For Investigating Radiological Contamination In Martha Oil Field. August 11, 2005. <http://www.kyrc.org/webnewspro/112381723236086.shtml>.) IDNR's definitions of "flowback water" and "produced water" are different. The two are distinguishably different enough that they are treated as separate types of fluid by both the Hydraulic Fracturing Regulatory Act and by the DNR Rules. Discharge of produced water onto the ground or into surface water or water drainage way is prohibited but it is not tested for radioactivity. This despite the fact that this fluid will be in contact with the naturally occurring radioactive elements in the ground for a longer period than the flowback and that it is much more likely to be radioactive. Problems: Failure to test produced water for radioactivity is problematic for a variety of reasons including: The health and safety of workers on the site who will be unaware of the levels of radioactivity they are being exposed to. The health and safety of workers transporting produced water who will also be in the dark regarding the levels of radioactivity they will be exposed to. The risk of storing radioactive material in tanks not created for storing radioactive materials. The risk of "recycling" produced water—radioactivity cannot be removed by recycling. The risk to the public in transporting radioactive materials Argonne National Laboratory recently cautioned about radiological doses: "It is commonly accepted that efforts should be undertaken at all times to keep radiological doses 'as low as reasonably achievable,' which is referred to as the ALARA principle or requirement." Overview of Radiological Dose and Risk Assessment (April 2011). DNR is failing to even adequately test for radioactivity and therefore, will not know the levels of radioactivity. How, then, can

## Fair Economy Illinois

---

DNR adequately protect workers and the general public? Elaboration: IDNR does not define a Fixed Date ( $\pm X$  days) for testing. Day 1, <Hour 1 test results will be orders of magnitude lower than either Day 2 or Day 10 tests results, and Day 10 tests results will be significantly lower than Day 80 ( $\pm 7$  days) results. Failure to specify a Fixed Test Date ( $\pm X$  days) renders test data so many irrelevant apples and oranges and allows companies to report suppressed, meaningless results by reporting Day 1, < 1 Hour data. The figure below, provided by the USGS, illustrates the nature of the problem. Please note that radium is not tested at Day 1, < 1 Hour. However, radium coprecipitates with barium, which is represented in total dissolved solids (TDS). It will therefore track TDS fairly closely. Conclusion: companies will be testing the very first flowback water to emerge from a fracked well. It will be Day 1, Minute 1 test results. 2.) There are two pits on a frack pad, one for "emergency" flowback and another, smaller one for drill cuttings and drilling mud. It is a basic principle in horizontal fracking to steer the drill bit through the horizontal strata with the highest gamma radiation readings (GAPI logs). The reason is that radioactivity correlates highly with total organic content (TOC) in the rock, and TOC correlates highly with oil and gas yields. This means that rock cuttings in the smaller drill mud and cuttings frack pit will often be more radioactive than flowback water. The IDNR knows this; yet it does not call for testing of drill bit pits as allowed under the Powers and duties section of the Act (§1- 15). 3.) The term "adjacent to" requires a "precise, clear standard" [IAPA, §100/5-20]. None is given. Does "adjacent to" mean 6 inches, 16 inches, 6 feet, 16 feet, or 60 feet? The IDNR does not say. 4.) Frack pad pipes and equipment can become incredibly radioactive over time. The very large temperature and pressure drops, as fluids move to the surface from thousands of feet underground, means that aqueous radioactive salts precipitate out as scale on pipes and equipment. The levels of radioactivity in pipe scale can exceed 100,000 picoCuries per gram and constitute a hazard to workers, or others who are exposed to recycled scrap metal from gas and oil operations. Yet, IDNR does not call on its General Assembly deferred "Power and authority" [Act, §1-15(e)] to test pipe, tanks, sludge, and equipment. This issue has been an issue in the oil and gas industry since the 1980s. If we faithfully follow applicable State and federal laws, Illinois can minimize the pernicious problems other states are going to face from the uncontrolled release of radioactive elements into their water and soil and work and non-work settings. We should prevent these problem from the start. Cleanup, after the oil and gas industry is gone, will be dreadfully expensive.. Recommendations: 1. Define the test date as = Day 21, the point at which increases in test results begin to level off. 2. Test for "radioactivity" in (1) flowback/produced water, (2) drill cuttings, soil "adjacent to" (3) storage tanks and (4) reserve pits, and (5) pipes and well pad equipment. 3. Define "adjacent to" as between 6 and 12 inches with test samples to be taken within the top 6 inches of soil 4. The rules should also require that the requirements of the Illinois Low Level Radioactivity Waste Management Act be followed.

Sincerely, Joseph Gary New York, IL 10003

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Act §1-75(a)7 requires radioactivity testing "once per well site" for (1) flowback water and ground "adjacent to" (2) storage tanks and (3) reserve pits. Act § 1-120 requires IDNR compliance with all "applicable federal, State, and local laws." One applicable State law is the Illinois Low-Level Radioactive Waste Management Act (PA 83-991 / 420ILCS20). Another is the Occupational Health and Safety Administration (OSHA) standards for workplace safety in settings with exposure to radioactivity (29 CFR 1910.1096). Rules §245.850(d)1-E and §245.850(e) are incomplete and deficient, and these inadequacies can "constitute a serious threat"--indeed, deadly threat-- "to the public interest, safety, or welfare" of Illinois citizens." Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Notably absent from these proposed rules is a requirement for the testing of "produced water", the fluid that returns from the well during the later stage of production (after flowback). Under the proposed rules, "produced water" can be stored on site and/or can be "recycled", yet there is no testing requirement. Naturally occurring radioactive material (NORM) is found in "produced water" also. See Technologically enhanced naturally occurring radioactive materials in the oil industry (TENORM), Nukleonika 2009; 54(1):3-9, and sources cited therein, especially for TENORM in produced water in the U.S., available at [http://www.nukleonika.pl/www/back/full/vol54\\_2009/v54n1p003f.pdf](http://www.nukleonika.pl/www/back/full/vol54_2009/v54n1p003f.pdf). See also NORM is also found on scale in oil pipes and on fracking equipment. (See Kentucky Resources Council Proposes Comprehensive Plan For Investigating Radiological Contamination In Martha Oil Field. August 11, 2005. <http://www.kyrc.org/webnewspro/112381723236086.shtml>.) IDNR's definitions of "flowback water" and "produced water" are different. The two are distinguishably different enough that they are treated as separate types of fluid by both the Hydraulic Fracturing Regulatory Act and by the DNR Rules. Discharge of produced water onto the ground or into surface water or water drainage way is prohibited but it is not tested for radioactivity. This despite the fact that this fluid will be in contact with the naturally occurring radioactive elements in the ground for a longer period than the flowback and that it is much more likely to be radioactive. Problems: Failure to test produced water for radioactivity is problematic for a variety of reasons including: The health and safety of workers on the site who will be unaware of the levels of radioactivity they are being exposed to. The health and safety of workers transporting produced water who will also be in the dark regarding the levels of radioactivity they will be exposed to. The risk of storing radioactive material in tanks not created for storing radioactive materials. The risk of "recycling" produced water—radioactivity cannot be removed by recycling. The risk to the public in transporting radioactive materials Argonne National Laboratory recently cautioned about radiological doses: "It is commonly accepted that efforts should be undertaken at all times to keep radiological doses 'as low as reasonably achievable,' which is referred to as the ALARA principle or requirement." Overview of Radiological Dose and Risk Assessment (April 2011). DNR is failing to even adequately test for radioactivity and therefore, will not know the levels of radioactivity. How, then, can

## Fair Economy Illinois

---

DNR adequately protect workers and the general public? Elaboration: IDNR does not define a Fixed Date ( $\pm X$  days) for testing. Day 1, <Hour 1 test results will be orders of magnitude lower than either Day 2 or Day 10 tests results, and Day 10 tests results will be significantly lower than Day 80 ( $\pm 7$  days) results. Failure to specify a Fixed Test Date ( $\pm X$  days) renders test data so many irrelevant apples and oranges and allows companies to report suppressed, meaningless results by reporting Day 1, < 1 Hour data. The figure below, provided by the USGS, illustrates the nature of the problem. Please note that radium is not tested at Day 1, < 1 Hour. However, radium coprecipitates with barium, which is represented in total dissolved solids (TDS). It will therefore track TDS fairly closely. Conclusion: companies will be testing the very first flowback water to emerge from a fracked well. It will be Day 1, Minute 1 test results. 2.) There are two pits on a frack pad, one for "emergency" flowback and another, smaller one for drill cuttings and drilling mud. It is a basic principle in horizontal fracking to steer the drill bit through the horizontal strata with the highest gamma radiation readings (GAPI logs). The reason is that radioactivity correlates highly with total organic content (TOC) in the rock, and TOC correlates highly with oil and gas yields. This means that rock cuttings in the smaller drill mud and cuttings frack pit will often be more radioactive than flowback water. The IDNR knows this; yet it does not call for testing of drill bit pits as allowed under the Powers and duties section of the Act (§1- 15). 3.) The term "adjacent to" requires a "precise, clear standard" [IAPA, §100/5-20]. None is given. Does "adjacent to" mean 6 inches, 16 inches, 6 feet, 16 feet, or 60 feet? The IDNR does not say. 4.) Frack pad pipes and equipment can become incredibly radioactive over time. The very large temperature and pressure drops, as fluids move to the surface from thousands of feet underground, means that aqueous radioactive salts precipitate out as scale on pipes and equipment. The levels of radioactivity in pipe scale can exceed 100,000 picoCuries per gram and constitute a hazard to workers, or others who are exposed to recycled scrap metal from gas and oil operations. Yet, IDNR does not call on its General Assembly deferred "Power and authority" [Act, §1-15(e)] to test pipe, tanks, sludge, and equipment. This issue has been an issue in the oil and gas industry since the 1980s. Consequences: According to studies by the Illinois State Geological Survey, the Illinois New Albany Shale Formation, the source rock for our oil and gas reserves, has above average levels of uranium (29 ppm). Uranium decays into radium and thence radon. Both uranium and radium are water soluble. As noted, the U.S. Geological Survey has found oil field brine or produced water in Southern Illinois to have Radium226 levels that average more than 1,000 picoCuries / liter (USGS 1999). That reading is 67 times above the maximum contamination level of the EPA. Radium226 has a half life of 1,600 years. Uranium228 has a half life of 4.468 billion years. If these water soluble salts leach into our aquifers, nearby communities will require--if possible--very expensive water treatment for the next 1,000 years. We may have to return to rainwater harvesting with the modern equivalent of cisterns. The radioactive levels for produced water from shale gas operations are likely to be 2 to 4 times higher than oilfield brine -- on average, 2,000 to 4,000 picoCuries per liter. In addition, radon levels in methane, propane, and ethane can be dangerously high. When it becomes commercial to extract shale gas from the SE corner of the state, major markets, such as Springfield and Chicago, will only be 0.9 and 1.4 days removed from shale gas wellheads. Even though radon222 has a half life of only 3.8 days, the closeness of major Illinois retail gas markets will mean that large number of people will be breathing in high levels of radon when they cook meals. The average level of indoor exposure to radon in Illinois is already 4.4

## Fair Economy Illinois

---

pCi/L ( American Lung Association 2013). The EPA maximum level--the point at which corrective action should be taken--is 4.0 pCi/L, and the preferred level is =3.0 pCi/L. The turn to shale gas, with its high levels of radon, will also turn a major Illinois public health problem in the wrong direction. Radioactive scale in pipe and equipment presents another problem; high levels of radioactivity have been found in school playground equipment and bleachers in school sports stadiums in Mississippi and Texas. Do we want untested oil and gas field scrap metal sold into Illinois markets? Do we want our children exposed on a daily basis to radioactive metal? The present rules creates no barriers to such an outcome. The problems cited above are why Illinois, with its large number of nuclear power plants, has a Low-Level Radioactive Waste Management Act. It and OSHA are the applicable State and Federal agencies with respect to the issue of radioactive waste and work safety standards in settings with exposure to radioactivity. If we faithfully follow applicable State and federal laws, Illinois can minimize the pernicious problems other states are going to face from the uncontrolled release of radioactive elements into their water and soil and work and non-work settings. We should prevent these problem from the start. Cleanup, after the oil and gas industry is gone, will be dreadfully expensive.. Recommendations: 1. Define the test date as = Day 21, the point at which increases in test results begin to level off. 2. Test for "radioactivity" in (1) flowback/produced water, (2) drill cuttings, soil "adjacent to" (3) storage tanks and (4) reserve pits, and (5) pipes and well pad equipment. 3. Define "adjacent to" as between 6 and 12 inches with test samples to be taken within the top 6 inches of soil 4. The rules should also require that the requirements of the Illinois Low Level Radioactivity Waste Management Act be followed.

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Act §1-75(a)7 requires radioactivity testing "once per well site" for (1) flowback water and ground "adjacent to" (2) storage tanks and (3) reserve pits. Act § 1-120 requires IDNR compliance with all "applicable federal, State, and local laws." One applicable State law is the Illinois Low-Level Radioactive Waste Management Act (PA 83-991 / 420ILCS20). Another is the Occupational Health and Safety Administration (OSHA) standards for workplace safety in settings with exposure to radioactivity (29 CFR 1910.1096). Rules §245.850(d)1-E and §245.850(e) are incomplete and deficient, and these inadequacies can "constitute a serious threat"--indeed, deadly threat-- "to the public interest, safety, or welfare" of Illinois citizens." Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Notably absent from these proposed rules is a requirement for the testing of "produced water", the fluid that returns from the well during the later stage of production (after flowback). Under the proposed rules, "produced water" can be stored on site and/or can be "recycled", yet there is no testing requirement. Naturally occurring radioactive material (NORM) is found in "produced water" also. See Technologically enhanced naturally occurring radioactive materials in the oil industry (TENORM), Nukleonika 2009; 54(1):3-9, and sources cited therein, especially for TENORM in produced water in the U.S., available at [http://www.nukleonika.pl/www/back/full/vol54\\_2009/v54n1p003f.pdf](http://www.nukleonika.pl/www/back/full/vol54_2009/v54n1p003f.pdf). See also NORM is also found on scale in oil pipes and on fracking equipment. (See Kentucky Resources Council Proposes Comprehensive Plan For Investigating Radiological Contamination In Martha Oil Field. August 11, 2005. <http://www.kyrc.org/webnewspro/112381723236086.shtml>.) IDNR's definitions of "flowback water" and "produced water" are different. The two are distinguishably different enough that they are treated as separate types of fluid by both the Hydraulic Fracturing Regulatory Act and by the DNR Rules. Discharge of produced water onto the ground or into surface water or water drainage way is prohibited but it is not tested for radioactivity. This despite the fact that this fluid will be in contact with the naturally occurring radioactive elements in the ground for a longer period than the flowback and that it is much more likely to be radioactive. Problems: Failure to test produced water for radioactivity is problematic for a variety of reasons including: The health and safety of workers on the site who will be unaware of the levels of radioactivity they are being exposed to. The health and safety of workers transporting produced water who will also be in the dark regarding the levels of radioactivity they will be exposed to. The risk of storing radioactive material in tanks not created for storing radioactive materials. The risk of "recycling" produced water—radioactivity cannot be removed by recycling. The risk to the public in transporting radioactive materials Argonne National Laboratory recently cautioned about radiological doses: "It is commonly accepted that efforts should be undertaken at all times to keep radiological doses 'as low as reasonably achievable,' which is referred to as the ALARA principle or requirement." Overview of Radiological Dose and Risk Assessment (April 2011). DNR is failing to even adequately test for radioactivity and therefore, will not know the levels of radioactivity. How, then, can

## Fair Economy Illinois

---

DNR adequately protect workers and the general public? Elaboration: IDNR does not define a Fixed Date ( $\pm X$  days) for testing. Day 1, <Hour 1 test results will be orders of magnitude lower than either Day 2 or Day 10 tests results, and Day 10 tests results will be significantly lower than Day 80 ( $\pm 7$  days) results. Failure to specify a Fixed Test Date ( $\pm X$  days) renders test data so many irrelevant apples and oranges and allows companies to report suppressed, meaningless results by reporting Day 1, < 1 Hour data. The figure below, provided by the USGS, illustrates the nature of the problem. Please note that radium is not tested at Day 1, < 1 Hour. However, radium coprecipitates with barium, which is represented in total dissolved solids (TDS). It will therefore track TDS fairly closely. Conclusion: companies will be testing the very first flowback water to emerge from a fracked well. It will be Day 1, Minute 1 test results. 2.) There are two pits on a frack pad, one for "emergency" flowback and another, smaller one for drill cuttings and drilling mud. It is a basic principle in horizontal fracking to steer the drill bit through the horizontal strata with the highest gamma radiation readings (GAPI logs). The reason is that radioactivity correlates highly with total organic content (TOC) in the rock, and TOC correlates highly with oil and gas yields. This means that rock cuttings in the smaller drill mud and cuttings frack pit will often be more radioactive than flowback water. The IDNR knows this; yet it does not call for testing of drill bit pits as allowed under the Powers and duties section of the Act (§1- 15). 3.) The term "adjacent to" requires a "precise, clear standard" [IAPA, §100/5-20]. None is given. Does "adjacent to" mean 6 inches, 16 inches, 6 feet, 16 feet, or 60 feet? The IDNR does not say. 4.) Frack pad pipes and equipment can become incredibly radioactive over time. The very large temperature and pressure drops, as fluids move to the surface from thousands of feet underground, means that aqueous radioactive salts precipitate out as scale on pipes and equipment. The levels of radioactivity in pipe scale can exceed 100,000 picoCuries per gram and constitute a hazard to workers, or others who are exposed to recycled scrap metal from gas and oil operations. Yet, IDNR does not call on its General Assembly deferred "Power and authority" [Act, §1-15(e)] to test pipe, tanks, sludge, and equipment. This issue has been an issue in the oil and gas industry since the 1980s. Consequences: According to studies by the Illinois State Geological Survey, the Illinois New Albany Shale Formation, the source rock for our oil and gas reserves, has above average levels of uranium (29 ppm). Uranium decays into radium and thence radon. Both uranium and radium are water soluble. As noted, the U.S. Geological Survey has found oil field brine or produced water in Southern Illinois to have Radium226 levels that average more than 1,000 picoCuries / liter (USGS 1999). That reading is 67 times above the maximum contamination level of the EPA. Radium226 has a half life of 1,600 years. Uranium228 has a half life of 4.468 billion years. If these water soluble salts leach into our aquifers, nearby communities will require--if possible--very expensive water treatment for the next 1,000 years. We may have to return to rainwater harvesting with the modern equivalent of cisterns. The radioactive levels for produced water from shale gas operations are likely to be 2 to 4 times higher than oilfield brine -- on average, 2,000 to 4,000 picoCuries per liter. In addition, radon levels in methane, propane, and ethane can be dangerously high. When it becomes commercial to extract shale gas from the SE corner of the state, major markets, such as Springfield and Chicago, will only be 0.9 and 1.4 days removed from shale gas wellheads. Even though radon222 has a half life of only 3.8 days, the closeness of major Illinois retail gas markets will mean that large number of people will be breathing in high levels of radon when they cook meals. The average level of indoor exposure to radon in Illinois is already 4.4

## Fair Economy Illinois

---

pCi/L ( American Lung Association 2013). The EPA maximum level--the point at which corrective action should be taken--is 4.0 pCi/L, and the preferred level is =3.0 pCi/L. The turn to shale gas, with its high levels of radon, will also turn a major Illinois public health problem in the wrong direction. Radioactive scale in pipe and equipment presents another problem; high levels of radioactivity have been found in school playground equipment and bleachers in school sports stadiums in Mississippi and Texas. Do we want untested oil and gas field scrap metal sold into Illinois markets? Do we want our children exposed on a daily basis to radioactive metal? The present rules creates no barriers to such an outcome. The problems cited above are why Illinois, with its large number of nuclear power plants, has a Low-Level Radioactive Waste Management Act. It and OSHA are the applicable State and Federal agencies with respect to the issue of radioactive waste and work safety standards in settings with exposure to radioactivity. If we faithfully follow applicable State and federal laws, Illinois can minimize the pernicious problems other states are going to face from the uncontrolled release of radioactive elements into their water and soil and work and non-work settings. We should prevent these problem from the start. Cleanup, after the oil and gas industry is gone, will be dreadfully expensive.. Recommendations: 1. Define the test date as = Day 21, the point at which increases in test results begin to level off. 2. Test for "radioactivity" in (1) flowback/produced water, (2) drill cuttings, soil "adjacent to" (3) storage tanks and (4) reserve pits, and (5) pipes and well pad equipment. 3. Define "adjacent to" as between 6 and 12 inches with test samples to be taken within the top 6 inches of soil 4. The rules should also require that the requirements of the Illinois Low Level Radioactivity Waste Management Act be followed.

Sincerely, Kathryn Chapman Hamburg, IL 62045

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Act §1-75(a)7 requires radioactivity testing "once per well site" for (1) flowback water and ground "adjacent to" (2) storage tanks and (3) reserve pits. Act § 1-120 requires IDNR compliance with all "applicable federal, State, and local laws." One applicable State law is the Illinois Low-Level Radioactive Waste Management Act (PA 83-991 / 420ILCS20). Another is the Occupational Health and Safety Administration (OSHA) standards for workplace safety in settings with exposure to radioactivity (29 CFR 1910.1096). Rules §245.850(d)1-E and §245.850(e) are incomplete and deficient, and these inadequacies can "constitute a serious threat"--indeed, deadly threat-- "to the public interest, safety, or welfare" of Illinois citizens." Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Notably absent from these proposed rules is a requirement for the testing of "produced water", the fluid that returns from the well during the later stage of production (after flowback). Under the proposed rules, "produced water" can be stored on site and/or can be "recycled", yet there is no testing requirement. Naturally occurring radioactive material (NORM) is found in "produced water" also. See Technologically enhanced naturally occurring radioactive materials in the oil industry (TENORM), Nukleonika 2009; 54(1):3-9, and sources cited therein, especially for TENORM in produced water in the U.S., available at [http://www.nukleonika.pl/www/back/full/vol54\\_2009/v54n1p003f.pdf](http://www.nukleonika.pl/www/back/full/vol54_2009/v54n1p003f.pdf). See also NORM is also found on scale in oil pipes and on fracking equipment. (See Kentucky Resources Council Proposes Comprehensive Plan For Investigating Radiological Contamination In Martha Oil Field. August 11, 2005. <http://www.kyrc.org/webnewspro/112381723236086.shtml>.) IDNR's definitions of "flowback water" and "produced water" are different. DNR adequately protect workers and the general public? Elaboration: IDNR does not define a Fixed Date ( $\pm X$  days) for testing. Day 1, <Hour 1 test results will be orders of magnitude lower than either Day 2 or Day 10 tests results, and Day 10 tests results will be significantly lower than Day 80 ( $\pm 7$  days) results. Failure to specify a Fixed Test Date ( $\pm X$  days) renders test data so many irrelevant apples and oranges and allows companies to report suppressed, meaningless results by reporting Day 1, < 1 Hour data. The figure below, provided by the USGS, illustrates the nature of the problem. Please note that radium is not tested at Day 1, < 1 Hour. However, radium coprecipitates with barium, which is represented in total dissolved solids (TDS). It will therefore track TDS fairly closely. Conclusion: companies will be testing the very first flowback water to emerge from a fracked well. It will be Day 1, Minute 1 test results. 2.) There are two pits on a frack pad, one for "emergency" flowback and another, smaller one for drill cuttings and drilling mud. It is a basic principle in horizontal fracking to steer the drill bit through the horizontal strata with the highest gamma radiation readings (GAPI logs). The reason is that radioactivity correlates highly with total organic content (TOC) in the rock, and TOC correlates highly with oil and gas yields. This means that rock cuttings in the smaller drill mud and cuttings frack pit will often be more radioactive than flowback water. The IDNR knows this; yet it does not call for testing of drill bit pits as allowed under the Powers and duties section of the Act (§1- 15). 3.) The term "adjacent to" requires a "precise, clear standard" [IAPA, §100/5-20]. None is given. Does "adjacent to" mean 6 inches, 16 inches, 6 feet, 16 feet, or 60 feet? The IDNR does not say. 4.) Frack pad pipes and equipment can become incredibly radioactive over time. The very large temperature and pressure drops, as fluids move to the surface from thousands of feet underground, means that aqueous radioactive salts precipitate out as scale on pipes and equipment. The levels of radioactivity in pipe scale can exceed 100,000 picoCuries per gram and constitute a hazard to workers, or others who are exposed to recycled scrap metal from gas and oil operations. Yet, IDNR does not call on its General Assembly deferred "Power and authority" [Act, §1-15(e)] to test pipe, tanks, sludge, and equipment. This issue has been an issue in the oil and gas industry since the 1980s. Consequences: According to studies by the Illinois State Geological Survey, the Illinois New Albany Shale Formation, the source rock for our oil and gas reserves, has above average levels of uranium (29 ppm). Uranium decays into radium and thence radon. Both uranium and radium are water soluble. As noted, the U.S. Geological Survey has found oil field brine or produced water in Southern Illinois to have Radium226 levels that average more than 1,000 picoCuries / liter (USGS 1999). That reading is 67 times above the maximum contamination level of the EPA. Radium226 has a half life of 1,600 years. Uranium228 has a half life of 4.468 billion years. If these water soluble salts leach into our aquifers, nearby communities will require--if possible--very expensive water treatment for the next 1,000 years. We may have to return to rainwater harvesting with the modern equivalent of cisterns. The radioactive levels for produced water from shale gas operations are likely to be 2 to 4 times higher than oilfield brine -- on average, 2,000 to 4,000 picoCuries per liter. In addition, radon levels in methane, propane, and ethane can be dangerously high. When it becomes commercial to extract shale gas from the SE corner of the state, major markets, such as Springfield and Chicago, will only be 0.9 and 1.4 days removed from shale gas wellheads. Even though radon222 has a half life of only 3.8 days, the closeness of major Illinois retail gas markets will mean that large number of people will be breathing in high levels of radon when they cook meals. The average level of indoor exposure to radon in Illinois is already 4.4

## Fair Economy Illinois

---

pCi/L ( American Lung Association 2013). The EPA maximum level--the point at which corrective action should be taken--is 4.0 pCi/L, and the preferred level is =3.0 pCi/L. The turn to shale gas, with its high levels of radon, will also turn a major Illinois public health problem in the wrong direction. Radioactive scale in pipe and equipment presents another problem; high levels of radioactivity have been found in school playground equipment and bleachers in school sports stadiums in Mississippi and Texas. Do we want untested oil and gas field scrap metal sold into Illinois markets? Do we want our children exposed on a daily basis to radioactive metal? The present rules creates no barriers to such an outcome. The problems cited above are why Illinois, with its large number of nuclear power plants, has a Low-Level Radioactive Waste Management Act. It and OSHA are the applicable State and Federal agencies with respect to the issue of radioactive waste and work safety standards in settings with exposure to radioactivity. If we faithfully follow applicable State and federal laws, Illinois can minimize the pernicious problems other states are going to face from the uncontrolled release of radioactive elements into their water and soil and work and non-work settings. We should prevent these problem from the start. Cleanup, after the oil and gas industry is gone, will be dreadfully expensive.. Recommendations: 1. Define the test date as = Day 21, the point at which increases in test results begin to level off. 2. Test for "radioactivity" in (1) flowback/produced water, (2) drill cuttings, soil "adjacent to" (3) storage tanks and (4) reserve pits, and (5) pipes and well pad equipment. 3. Define "adjacent to" as between 6 and 12 inches with test samples to be taken within the top 6 inches of soil 4. The rules should also require that the requirements of the Illinois Low Level Radioactivity Waste Management Act be followed.

Sincerely, Kathy Machaj Chicago, IL 60607

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Act §1-75(a)7 requires radioactivity testing "once per well site" for (1) flowback water and ground "adjacent to" (2) storage tanks and (3) reserve pits. Act § 1-120 requires IDNR compliance with all "applicable federal, State, and local laws." One applicable State law is the Illinois Low-Level Radioactive Waste Management Act (PA 83-991 / 420ILCS20). Another is the Occupational Health and Safety Administration (OSHA) standards for workplace safety in settings with exposure to radioactivity (29 CFR 1910.1096). Rules §245.850(d)1-E and §245.850(e) are incomplete and deficient, and these inadequacies can "constitute a serious threat"--indeed, deadly threat-- "to the public interest, safety, or welfare" of Illinois citizens." Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Notably absent from these proposed rules is a requirement for the testing of "produced water", the fluid that returns from the well during the later stage of production (after flowback). Under the proposed rules, "produced water" can be stored on site and/or can be "recycled", yet there is no testing requirement. Naturally occurring radioactive material (NORM) is found in "produced water" also. See Technologically enhanced naturally occurring radioactive materials in the oil industry (TENORM), Nukleonika 2009; 54(1):3-9, and sources cited therein, especially for TENORM in produced water in the U.S., available at [http://www.nukleonika.pl/www/back/full/vol54\\_2009/v54n1p003f.pdf](http://www.nukleonika.pl/www/back/full/vol54_2009/v54n1p003f.pdf). See also NORM is also found on scale in oil pipes and on fracking equipment. (See Kentucky Resources Council Proposes Comprehensive Plan For Investigating Radiological Contamination In Martha Oil Field. August 11, 2005. <http://www.kyrc.org/webnewspro/112381723236086.shtml>.) IDNR's definitions of "flowback water" and "produced water" are different. The two are distinguishably different enough that they are treated as separate types of fluid by both the Hydraulic Fracturing Regulatory Act and by the DNR Rules. Discharge of produced water onto the ground or into surface water or water drainage way is prohibited but it is not tested for radioactivity. This despite the fact that this fluid will be in contact with the naturally occurring radioactive elements in the ground for a longer period than the flowback and that it is much more likely to be radioactive. Problems: Failure to test produced water for radioactivity is problematic for a variety of reasons including: The health and safety of workers on the site who will be unaware of the levels of radioactivity they are being exposed to. The health and safety of workers transporting produced water who will also be in the dark regarding the levels of radioactivity they will be exposed to. The risk of storing radioactive material in tanks not created for storing radioactive materials. The risk of "recycling" produced water—radioactivity cannot be removed by recycling. The risk to the public in transporting radioactive materials Argonne National Laboratory recently cautioned about radiological doses: "It is commonly accepted that efforts should be undertaken at all times to keep radiological doses 'as low as reasonably achievable,' which is referred to as the ALARA principle or requirement." Overview of Radiological Dose and Risk Assessment (April 2011). DNR is failing to even adequately test for radioactivity and therefore, will not know the levels of radioactivity. How, then, can

## Fair Economy Illinois

---

DNR adequately protect workers and the general public? Elaboration: IDNR does not define a Fixed Date ( $\pm X$  days) for testing. Day 1, <Hour 1 test results will be orders of magnitude lower than either Day 2 or Day 10 tests results, and Day 10 tests results will be significantly lower than Day 80 ( $\pm 7$  days) results. Failure to specify a Fixed Test Date ( $\pm X$  days) renders test data so many irrelevant apples and oranges and allows companies to report suppressed, meaningless results by reporting Day 1, < 1 Hour data. The figure below, provided by the USGS, illustrates the nature of the problem. Please note that radium is not tested at Day 1, < 1 Hour. However, radium coprecipitates with barium, which is represented in total dissolved solids (TDS). It will therefore track TDS fairly closely. Conclusion: companies will be testing the very first flowback water to emerge from a fracked well. It will be Day 1, Minute 1 test results. 2.) There are two pits on a frack pad, one for "emergency" flowback and another, smaller one for drill cuttings and drilling mud. It is a basic principle in horizontal fracking to steer the drill bit through the horizontal strata with the highest gamma radiation readings (GAPI logs). The reason is that radioactivity correlates highly with total organic content (TOC) in the rock, and TOC correlates highly with oil and gas yields. DNR adequately protect workers and the general public? Elaboration: IDNR does not define a Fixed Date ( $\pm X$  days) for testing. Day 1, <Hour 1 test results will be orders of magnitude lower than either Day 2 or Day 10 tests results, and Day 10 tests results will be significantly lower than Day 80 ( $\pm 7$  days) results. Failure to specify a Fixed Test Date ( $\pm X$  days) renders test data so many irrelevant apples and oranges and allows companies to report suppressed, meaningless results by reporting Day 1, < 1 Hour data. The figure below, provided by the USGS, illustrates the nature of the problem. Please note that radium is not tested at Day 1, < 1 Hour. However, radium coprecipitates with barium, which is represented in total dissolved solids (TDS). It will therefore track TDS fairly closely. Conclusion: companies will be testing the very first flowback water to emerge from a fracked well. It will be Day 1, Minute 1 test results. 2.) There are two pits on a frack pad, one for "emergency" flowback and another, smaller one for drill cuttings and drilling mud. It is a basic principle in horizontal fracking to steer the drill bit through the horizontal strata with the highest gamma radiation readings (GAPI logs). The reason is that radioactivity correlates highly with total organic content (TOC) in the rock, and TOC correlates highly with oil and gas yields. This means that rock cuttings in the smaller drill mud and cuttings frack pit will often be more radioactive than flowback water. The IDNR knows this; yet it does not call for testing of drill bit pits as allowed under the Powers and duties section of the Act (§1- 15). 3.) The term "adjacent to" requires a "precise, clear standard" [IAPA, §100/5-20]. None is given. Does "adjacent to" mean 6 inches, 16 inches, 6 feet, 16 feet, or 60 feet? The IDNR does not say. 4.) Frack pad pipes and equipment can become incredibly radioactive over time. The very large temperature and pressure drops, as fluids move to the surface from thousands of feet underground, means that aqueous radioactive salts precipitate out as scale on pipes and equipment. The levels of radioactivity in pipe scale can exceed 100,000 picoCuries per gram and constitute a hazard to workers, or others who are exposed to recycled scrap metal from gas and oil operations. Yet, IDNR does not call on its General Assembly deferred "Power and authority" [Act, §1-15(e)] to test pipe, tanks, sludge, and equipment. This issue has been an issue in the oil and gas industry since the 1980s. Consequences: According to studies by the Illinois State Geological Survey, the Illinois New Albany Shale Formation, the source rock for our oil and gas reserves, has above average levels of uranium (29 ppm). Uranium decays into radium and thence radon. Both uranium and radium are water soluble. As noted, the U.S. Geological Survey has found oil field brine or produced water in Southern Illinois to have Radium226 levels that average more than 1,000 picoCuries / liter (USGS 1999). That reading is 67 times above the maximum contamination level of the EPA. Radium226 has a half life of 1,600 years. Uranium228 has a half life of 4.468 billion years. If these water soluble salts leach into our aquifers, nearby communities will require--if possible--very expensive water treatment for the next 1,000 years. We may have to return to rainwater harvesting with the modern equivalent of cisterns. The radioactive levels for produced water from shale gas operations are likely to be 2 to 4 times higher than oilfield brine -- on average, 2,000 to 4,000 picoCuries per liter. In addition, radon levels in methane, propane, and ethane can be dangerously high. When it becomes commercial to extract shale gas from the SE corner of the state, major markets, such as Springfield and Chicago, will only be 0.9 and 1.4 days removed from shale gas wellheads. Even though radon222 has a half life of only 3.8 days, the closeness of major Illinois retail gas markets will mean that large number of people will be breathing in high levels of radon when they cook meals. The average level of indoor exposure to radon in Illinois is already 4.4

## Fair Economy Illinois

---

pCi/L ( American Lung Association 2013). The EPA maximum level--the point at which corrective action should be taken--is 4.0 pCi/L, and the preferred level is =3.0 pCi/L. The turn to shale gas, with its high levels of radon, will also turn a major Illinois public health problem in the wrong direction. Radioactive scale in pipe and equipment presents another problem; high levels of radioactivity have been found in school playground equipment and bleachers in school sports stadiums in Mississippi and Texas. Do we want untested oil and gas field scrap metal sold into Illinois markets? Do we want our children exposed on a daily basis to radioactive metal? The present rules creates no barriers to such an outcome. The problems cited above are why Illinois, with its large number of nuclear power plants, has a Low-Level Radioactive Waste Management Act. It and OSHA are the applicable State and Federal agencies with respect to the issue of radioactive waste and work safety standards in settings with exposure to radioactivity. If we faithfully follow applicable State and federal laws, Illinois can minimize the pernicious problems other states are going to face from the uncontrolled release of radioactive elements into their water and soil and work and non-work settings. We should prevent these problem from the start. Cleanup, after the oil and gas industry is gone, will be dreadfully expensive.. Recommendations: 1. Define the test date as = Day 21, the point at which increases in test results begin to level off. 2. Test for "radioactivity" in (1) flowback/produced water, (2) drill cuttings, soil "adjacent to" (3) storage tanks and (4) reserve pits, and (5) pipes and well pad equipment. 3. Define "adjacent to" as between 6 and 12 inches with test samples to be taken within the top 6 inches of soil 4. The rules should also require that the requirements of the Illinois Low Level Radioactivity Waste Management Act be followed.

Sincerely, Kelsey Chicago, IL 60631

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Act §1-75(a)7 requires radioactivity testing "once per well site" for (1) flowback water and ground "adjacent to" (2) storage tanks and (3) reserve pits. Act § 1-120 requires IDNR compliance with all "applicable federal, State, and local laws." One applicable State law is the Illinois Low-Level Radioactive Waste Management Act (PA 83-991 / 420ILCS20). Another is the Occupational Health and Safety Administration (OSHA) standards for workplace safety in settings with exposure to radioactivity (29 CFR 1910.1096). Rules §245.850(d)1-E and §245.850(e) are incomplete and deficient, and these inadequacies can "constitute a serious threat"--indeed, deadly threat-- "to the public interest, safety, or welfare" of Illinois citizens." Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Notably absent from these proposed rules is a requirement for the testing of "produced water", the fluid that returns from the well during the later stage of production (after flowback). Under the proposed rules, "produced water" can be stored on site and/or can be "recycled", yet there is no testing requirement. Naturally occurring radioactive material (NORM) is found in "produced water" also. See Technologically enhanced naturally occurring radioactive materials in the oil industry (TENORM), Nukleonika 2009; 54(1):3-9, and sources cited therein, especially for TENORM in produced water in the U.S., available at [http://www.nukleonika.pl/www/back/full/vol54\\_2009/v54n1p003f.pdf](http://www.nukleonika.pl/www/back/full/vol54_2009/v54n1p003f.pdf). See also NORM is also found on scale in oil pipes and on fracking equipment. (See Kentucky Resources Council Proposes Comprehensive Plan For Investigating Radiological Contamination In Martha Oil Field. August 11, 2005. <http://www.kyrc.org/webnewspro/112381723236086.shtml>.) IDNR's definitions of "flowback water" and "produced water" are different. The two are distinguishably different enough that they are treated as separate types of fluid by both the Hydraulic Fracturing Regulatory Act and by the DNR Rules. Discharge of produced water onto the ground or into surface water or water drainage way is prohibited but it is not tested for radioactivity. This despite the fact that this fluid will be in contact with the naturally occurring radioactive elements in the ground for a longer period than the flowback and that it is much more likely to be radioactive. Problems: Failure to test produced water for radioactivity is problematic for a variety of reasons including: The health and safety of workers on the site who will be unaware of the levels of radioactivity they are being exposed to. The health and safety of workers transporting produced water who will also be in the dark regarding the levels of radioactivity they will be exposed to. The risk of storing radioactive material in tanks not created for storing radioactive materials. The risk of "recycling" produced water—radioactivity cannot be removed by recycling. The risk to the public in transporting radioactive materials Argonne National Laboratory recently cautioned about radiological doses: "It is commonly accepted that efforts should be undertaken at all times to keep radiological doses 'as low as reasonably achievable,' which is referred to as the ALARA principle or requirement." Overview of Radiological Dose and Risk Assessment (April 2011). DNR is failing to even adequately test for radioactivity and therefore, will not know the levels of radioactivity. How, then, can

## Fair Economy Illinois

---

DNR adequately protect workers and the general public? Elaboration: IDNR does not define a Fixed Date ( $\pm X$  days) for testing. Day 1, <Hour 1 test results will be orders of magnitude lower than either Day 2 or Day 10 tests results, and Day 10 tests results will be significantly lower than Day 80 ( $\pm 7$  days) results. Failure to specify a Fixed Test Date ( $\pm X$  days) renders test data so many irrelevant apples and oranges and allows companies to report suppressed, meaningless results by reporting Day 1, < 1 Hour data. The figure below, provided by the USGS, illustrates the nature of the problem. Please note that radium is not tested at Day 1, < 1 Hour. However, radium coprecipitates with barium, which is represented in total dissolved solids (TDS). It will therefore track TDS fairly closely. Conclusion: companies will be testing the very first flowback water to emerge from a fracked well. It will be Day 1, Minute 1 test results. 2.) There are two pits on a frack pad, one for "emergency" flowback and another, smaller one for drill cuttings and drilling mud. It is a basic principle in horizontal fracking to steer the drill bit through the horizontal strata with the highest gamma radiation readings (GAPI logs). The reason is that radioactivity correlates highly with total organic content (TOC) in the rock, and TOC correlates highly with oil and gas yields. This means that rock cuttings in the smaller drill mud and cuttings frack pit will often be more radioactive than flowback water. The IDNR knows this; yet it does not call for testing of drill bit pits as allowed under the Powers and duties section of the Act (§1- 15). 3.) The term "adjacent to" requires a "precise, clear standard" [IAPA, §100/5-20]. None is given. Does "adjacent to" mean 6 inches, 16 inches, 6 feet, 16 feet, or 60 feet? The IDNR does not say. 4.) Frack pad pipes and equipment can become incredibly radioactive over time. The very large temperature and pressure drops, as fluids move to the surface from thousands of feet underground, means that aqueous radioactive salts precipitate out as scale on pipes and equipment. The levels of radioactivity in pipe scale can exceed 100,000 picoCuries per gram and constitute a hazard to workers, or others who are exposed to recycled scrap metal from gas and oil operations. Yet, IDNR does not call on its General Assembly deferred "Power and authority" [Act, §1-15(e)] to test pipe, tanks, sludge, and equipment. This issue has been an issue in the oil and gas industry since the 1980s. Consequences: According to studies by the Illinois State Geological Survey, the Illinois New Albany Shale Formation, the source rock for our oil and gas reserves, has above average levels of uranium (29 ppm). Uranium decays into radium and thence radon. Both uranium and radium are water soluble. As noted, the U.S. Geological Survey has found oil field brine or produced water in Southern Illinois to have Radium226 levels that average more than 1,000 picoCuries / liter (USGS 1999). That reading is 67 times above the maximum contamination level of the EPA. Radium226 has a half life of 1,600 years. Uranium228 has a half life of 4.468 billion years. If these water soluble salts leach into our aquifers, nearby communities will require--if possible--very expensive water treatment for the next 1,000 years. We may have to return to rainwater harvesting with the modern equivalent of cisterns. The radioactive levels for produced water from shale gas operations are likely to be 2 to 4 times higher than oilfield brine -- on average, 2,000 to 4,000 picoCuries per liter. In addition, radon levels in methane, propane, and ethane can be dangerously high. When it becomes commercial to extract shale gas from the SE corner of the state, major markets, such as Springfield and Chicago, will only be 0.9 and 1.4 days removed from shale gas wellheads. Even though radon222 has a half life of only 3.8 days, the closeness of major Illinois retail gas markets will mean that large number of people will be breathing in high levels of radon when they cook meals. The average level of indoor exposure to radon in Illinois is already 4.4

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Act §1-75(a)7 requires radioactivity testing "once per well site" for (1) flowback water and ground "adjacent to" (2) storage tanks and (3) reserve pits. Act § 1-120 requires IDNR compliance with all "applicable federal, State, and local laws." One applicable State law is the Illinois Low-Level Radioactive Waste Management Act (PA 83-991 / 420ILCS20). Another is the Occupational Health and Safety Administration (OSHA) standards for workplace safety in settings with exposure to radioactivity (29 CFR 1910.1096). Rules §245.850(d)1-E and §245.850(e) are incomplete and deficient, and these inadequacies can "constitute a serious threat"--indeed, deadly threat-- "to the public interest, safety, or welfare" of Illinois citizens." Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Notably absent from these proposed rules is a requirement for the testing of "produced water", the fluid that returns from the well during the later stage of production (after flowback). Under the proposed rules, "produced water" can be stored on site and/or can be "recycled", yet there is no testing requirement. Naturally occurring radioactive material (NORM) is found in "produced water" also. See Technologically enhanced naturally occurring radioactive materials in the oil industry (TENORM), Nukleonika 2009; 54(1):3-9, and sources cited therein, especially for TENORM in produced water in the U.S., available at [http://www.nukleonika.pl/www/back/full/vol54\\_2009/v54n1p003f.pdf](http://www.nukleonika.pl/www/back/full/vol54_2009/v54n1p003f.pdf). See also NORM is also found on scale in oil pipes and on fracking equipment. (See Kentucky Resources Council Proposes Comprehensive Plan For Investigating Radiological Contamination In Martha Oil Field. August 11, 2005. <http://www.kyrc.org/webnewspro/112381723236086.shtml>.) IDNR's definitions of "flowback water" and "produced water" are different. The two are distinguishably different enough that they are treated as separate types of fluid by both the Hydraulic Fracturing Regulatory Act and by the DNR Rules. Discharge of produced water onto the ground or into surface water or water drainage way is prohibited but it is not tested for radioactivity. This despite the fact that this fluid will be in contact with the naturally occurring radioactive elements in the ground for a longer period than the flowback and that it is much more likely to be radioactive. Problems: Failure to test produced water for radioactivity is problematic for a variety of reasons including: The health and safety of workers on the site who will be unaware of the levels of radioactivity they are being exposed to. The health and safety of workers transporting produced water who will also be in the dark regarding the levels of radioactivity they will be exposed to. The risk of storing radioactive material in tanks not created for storing radioactive materials. The risk of "recycling" produced water—radioactivity cannot be removed by recycling. The risk to the public in transporting radioactive materials Argonne National Laboratory recently cautioned about radiological doses: "It is commonly accepted that efforts should be undertaken at all times to keep radiological doses 'as low as reasonably achievable,' which is referred to as the ALARA principle or requirement." Overview of Radiological Dose and Risk Assessment (April 2011). DNR is failing to even adequately test for radioactivity and therefore, will not know the levels of radioactivity. How, then, can

## Fair Economy Illinois

---

DNR adequately protect workers and the general public? Elaboration: IDNR does not define a Fixed Date ( $\pm X$  days) for testing. Day 1, <Hour 1 test results will be orders of magnitude lower than either Day 2 or Day 10 tests results, and Day 10 tests results will be significantly lower than Day 80 ( $\pm 7$  days) results. Failure to specify a Fixed Test Date ( $\pm X$  days) renders test data so many irrelevant apples and oranges and allows companies to report suppressed, meaningless results by reporting Day 1, < 1 Hour data. The figure below, provided by the USGS, illustrates the nature of the problem. Please note that radium is not tested at Day 1, < 1 Hour. However, radium coprecipitates with barium, which is represented in total dissolved solids (TDS). It will therefore track TDS fairly closely. Conclusion: companies will be testing the very first flowback water to emerge from a fracked well. It will be Day 1, Minute 1 test results. 2.) There are two pits on a frack pad, one for "emergency" flowback and another, smaller one for drill cuttings and drilling mud. It is a basic principle in horizontal fracking to steer the drill bit through the horizontal strata with the highest gamma radiation readings (GAPI logs). The reason is that radioactivity correlates highly with total organic content (TOC) in the rock, and TOC correlates highly with oil and gas yields. This means that rock cuttings in the smaller drill mud and cuttings frack pit will often be more radioactive than flowback water. The IDNR knows this; yet it does not call for testing of drill bit pits as allowed under the Powers and duties section of the Act (§1- 15). 3.) The term "adjacent to" requires a "precise, clear standard" [IAPA, §100/5-20]. None is given. Does "adjacent to" mean 6 inches, 16 inches, 6 feet, 16 feet, or 60 feet? The IDNR does not say. 4.) Frack pad pipes and equipment can become incredibly radioactive over time. The very large temperature and pressure drops, as fluids move to the surface from thousands of feet underground, means that aqueous radioactive salts precipitate out as scale on pipes and equipment. The levels of radioactivity in pipe scale can exceed 100,000 picoCuries per gram and constitute a hazard to workers, or others who are exposed to recycled scrap metal from gas and oil operations. Yet, IDNR does not call on its General Assembly deferred "Power and authority" [Act, §1-15(e)] to test pipe, tanks, sludge, and equipment. This issue has been an issue in the oil and gas industry since the 1980s. Consequences: According to studies by the Illinois State Geological Survey, the Illinois New Albany Shale Formation, the source rock for our oil and gas reserves, has above average levels of uranium (29 ppm). Uranium decays into radium and thence radon. Both uranium and radium are water soluble. As noted, the U.S. Geological Survey has found oil field brine or produced water in Southern Illinois to have Radium226 levels that average more than 1,000 picoCuries / liter (USGS 1999). That reading is 67 times above the maximum contamination level of the EPA. Radium226 has a half life of 1,600 years. Uranium228 has a half life of 4.468 billion years. If these water soluble salts leach into our aquifers, nearby communities will require--if possible--very expensive water treatment for the next 1,000 years. We may have to return to rainwater harvesting with the modern equivalent of cisterns. The radioactive levels for produced water from shale gas operations are likely to be 2 to 4 times higher than oilfield brine -- on average, 2,000 to 4,000 picoCuries per liter. In addition, radon levels in methane, propane, and ethane can be dangerously high. When it becomes commercial to extract shale gas from the SE corner of the state, major markets, such as Springfield and Chicago, will only be 0.9 and 1.4 days removed from shale gas wellheads. Even though radon222 has a half life of only 3.8 days, the closeness of major Illinois retail gas markets will mean that large number of people will be breathing in high levels of radon when they cook meals. The average level of indoor exposure to radon in Illinois is already 4.4

## Fair Economy Illinois

---

pCi/L ( American Lung Association 2013). The EPA maximum level--the point at which corrective action should be taken--is 4.0 pCi/L, and the preferred level is =3.0 pCi/L. The turn to shale gas, with its high levels of radon, will also turn a major Illinois public health problem in the wrong direction. Radioactive scale in pipe and equipment presents another problem; high levels of radioactivity have been found in school playground equipment and bleachers in school sports stadiums in Mississippi and Texas. Do we want untested oil and gas field scrap metal sold into Illinois markets? Do we want our children exposed on a daily basis to radioactive metal? The present rules creates no barriers to such an outcome. The problems cited above are why Illinois, with its large number of nuclear power plants, has a Low-Level Radioactive Waste Management Act. It and OSHA are the applicable State and Federal agencies with respect to the issue of radioactive waste and work safety standards in settings with exposure to radioactivity. If we faithfully follow applicable State and federal laws, Illinois can minimize the pernicious problems other states are going to face from the uncontrolled release of radioactive elements into their water and soil and work and non-work settings. We should prevent these problem from the start. Cleanup, after the oil and gas industry is gone, will be dreadfully expensive.. Recommendations: 1. Define the test date as = Day 21, the point at which increases in test results begin to level off. 2. Test for "radioactivity" in (1) flowback/produced water, (2) drill cuttings, soil "adjacent to" (3) storage tanks and (4) reserve pits, and (5) pipes and well pad equipment. 3. Define "adjacent to" as between 6 and 12 inches with test samples to be taken within the top 6 inches of soil 4. The rules should also require that the requirements of the Illinois Low Level Radioactivity Waste Management Act be followed.

Sincerely, Kris Chatterjee Chicago, IL 60637

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Act §1-75(a)7 requires radioactivity testing "once per well site" for (1) flowback water and ground "adjacent to" (2) storage tanks and (3) reserve pits. Act § 1-120 requires IDNR compliance with all "applicable federal, State, and local laws." One applicable State law is the Illinois Low-Level Radioactive Waste Management Act (PA 83-991 / 420ILCS20). Another is the Occupational Health and Safety Administration (OSHA) standards for workplace safety in settings with exposure to radioactivity (29 CFR 1910.1096). Rules §245.850(d)1-E and §245.850(e) are incomplete and deficient, and these inadequacies can "constitute a serious threat"--indeed, deadly threat-- "to the public interest, safety, or welfare" of Illinois citizens." Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Notably absent from these proposed rules is a requirement for the testing of "produced water", the fluid that returns from the well during the later stage of production (after flowback). Under the proposed rules, "produced water" can be stored on site and/or can be "recycled", yet there is no testing requirement. Naturally occurring radioactive material (NORM) is found in "produced water" also. See Technologically enhanced naturally occurring radioactive materials in the oil industry (TENORM), Nukleonika 2009; 54(1):3-9, and sources cited therein, especially for TENORM in produced water in the U.S., available at [http://www.nukleonika.pl/www/back/full/vol54\\_2009/v54n1p003f.pdf](http://www.nukleonika.pl/www/back/full/vol54_2009/v54n1p003f.pdf). See also NORM is also found on scale in oil pipes and on fracking equipment. (See Kentucky Resources Council Proposes Comprehensive Plan For Investigating Radiological Contamination In Martha Oil Field. August 11, 2005. <http://www.kyrc.org/webnewspro/112381723236086.shtml>.) IDNR's definitions of "flowback water" and "produced water" are different. The two are distinguishably different enough that they are treated as separate types of fluid by both the Hydraulic Fracturing Regulatory Act and by the DNR Rules. Discharge of produced water onto the ground or into surface water or water drainage way is prohibited but it is not tested for radioactivity. This despite the fact that this fluid will be in contact with the naturally occurring radioactive elements in the ground for a longer period than the flowback and that it is much more likely to be radioactive. Problems: Failure to test produced water for radioactivity is problematic for a variety of reasons including: The health and safety of workers on the site who will be unaware of the levels of radioactivity they are being exposed to. The health and safety of workers transporting produced water who will also be in the dark regarding the levels of radioactivity they will be exposed to. The risk of storing radioactive material in tanks not created for storing radioactive materials. The risk of "recycling" produced water—radioactivity cannot be removed by recycling. The risk to the public in transporting radioactive materials Argonne National Laboratory recently cautioned about radiological doses: "It is commonly accepted that efforts should be undertaken at all times to keep radiological doses 'as low as reasonably achievable,' which is referred to as the ALARA principle or requirement." Overview of Radiological Dose and Risk Assessment (April 2011). DNR is failing to even adequately test for radioactivity and therefore, will not know the levels of radioactivity. How, then, can

DNR adequately protect workers and the general public? Elaboration: IDNR does not define a Fixed Date ( $\pm X$  days) for testing. Day 1, <Hour 1 test results will be orders of magnitude lower than either Day 2 or Day 10 tests results, and Day 10 tests results will be significantly lower than Day 80 ( $\pm 7$  days) results. Failure to specify a Fixed Test Date ( $\pm X$  days) renders test data so many irrelevant apples and oranges and allows companies to report suppressed, meaningless results by reporting Day 1, < 1 Hour data. The figure below, provided by the USGS, illustrates the nature of the problem. Please note that radium is not tested at Day 1, < 1 Hour. However, radium coprecipitates with barium, which is represented in total dissolved solids (TDS). It will therefore track TDS fairly closely. Conclusion: companies will be testing the very first flowback water to emerge from a fracked well. It will be Day 1, Minute 1 test results. 2.) There are two pits on a frack pad, one for "emergency" flowback and another, smaller one for drill cuttings and drilling mud. It is a basic principle in horizontal fracking to steer the drill bit through the horizontal strata with the highest gamma radiation readings (GAPI logs). The reason is that radioactivity correlates highly with total organic content (TOC) in the rock, and TOC correlates highly with oil and gas yields. This means that rock cuttings in the smaller drill mud and cuttings frack pit will often be more radioactive than flowback water. The IDNR knows this; yet it does not call for testing of drill bit pits as allowed under the Powers and duties section of the Act (§1- 15). 3.) The term "adjacent to" requires a "precise, clear standard" [IAPA, §100/5-20]. None is given. Does "adjacent to" mean 6 inches, 16 inches, 6 feet, 16 feet, or 60 feet? The IDNR does not say. 4.) Frack pad pipes and equipment can become incredibly radioactive over time. The very large temperature and pressure drops, as fluids move to the surface from thousands of feet underground, means that aqueous radioactive salts precipitate out as scale on pipes and equipment. The levels of radioactivity in pipe scale can exceed 100,000 picoCuries per gram and constitute a hazard to workers, or others who are exposed to recycled scrap metal from gas and oil operations. Yet, IDNR does not call on its General Assembly deferred "Power and authority" [Act, §1-15(e)] to test pipe, tanks, sludge, and equipment. This issue has been an issue in the oil and gas industry since the 1980s. Consequences: According to studies by the Illinois State Geological Survey, the Illinois New Albany Shale Formation, the source rock for our oil and gas reserves, has above average levels of uranium (29 ppm). Uranium decays into radium and thence radon. Both uranium and radium are water soluble. As noted, the U.S. Geological Survey has found oil field brine or produced water in Southern Illinois to have Radium226 levels that average more than 1,000 picoCuries / liter (USGS 1999). That reading is 67 times above the maximum contamination level of the EPA. Radium226 has a half life of 1,600 years. Uranium228 has a half life of 4.468 billion years. If these water soluble salts leach into our aquifers, nearby communities will require--if possible--very expensive water treatment for the next 1,000 years. We may have to return to rainwater harvesting with the modern equivalent of cisterns. The radioactive levels for produced water from shale gas operations are likely to be 2 to 4 times higher than oilfield brine -- on average, 2,000 to 4,000 picoCuries per liter. In addition, radon levels in methane, propane, and ethane can be dangerously high. When it becomes commercial to extract shale gas from the SE corner of the state, major markets, such as Springfield and Chicago, will only be 0.9 and 1.4 days removed from shale gas wellheads. Even though radon222 has a half life of only 3.8 days, the closeness of major Illinois retail gas markets will mean that large number of people will be breathing in high levels of radon when they cook meals. The average level of indoor exposure to radon in Illinois is already 4.4

## Fair Economy Illinois

---

pCi/L ( American Lung Association 2013). The EPA maximum level--the point at which corrective action should be taken--is 4.0 pCi/L, and the preferred level is =3.0 pCi/L. The turn to shale gas, with its high levels of radon, will also turn a major Illinois public health problem in the wrong direction. Radioactive scale in pipe and equipment presents another problem; high levels of radioactivity have been found in school playground equipment and bleachers in school sports stadiums in Mississippi and Texas. Do we want untested oil and gas field scrap metal sold into Illinois markets? Do we want our children exposed on a daily basis to radioactive metal? The present rules creates no barriers to such an outcome. The problems cited above are why Illinois, with its large number of nuclear power plants, has a Low-Level Radioactive Waste Management Act. It and OSHA are the applicable State and Federal agencies with respect to the issue of radioactive waste and work safety standards in settings with exposure to radioactivity. If we faithfully follow applicable State and federal laws, Illinois can minimize the pernicious problems other states are going to face from the uncontrolled release of radioactive elements into their water and soil and work and non-work settings. We should prevent these problem from the start. Cleanup, after the oil and gas industry is gone, will be dreadfully expensive.. Recommendations: 1. Define the test date as = Day 21, the point at which increases in test results begin to level off. 2. Test for "radioactivity" in (1) flowback/produced water, (2) drill cuttings, soil "adjacent to" (3) storage tanks and (4) reserve pits, and (5) pipes and well pad equipment. 3. Define "adjacent to" as between 6 and 12 inches with test samples to be taken within the top 6 inches of soil 4. The rules should also require that the requirements of the Illinois Low Level Radioactivity Waste Management Act be followed.

Sincerely, Lavine Hemlani Chicago, IL 60637

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Act §1-75(a)7 requires radioactivity testing "once per well site" for (1) flowback water and ground "adjacent to" (2) storage tanks and (3) reserve pits. Act § 1-120 requires IDNR compliance with all "applicable federal, State, and local laws." One applicable State law is the Illinois Low-Level Radioactive Waste Management Act (PA 83-991 / 420ILCS20). Another is the Occupational Health and Safety Administration (OSHA) standards for workplace safety in settings with exposure to radioactivity (29 CFR 1910.1096). Rules §245.850(d)1-E and §245.850(e) are incomplete and deficient, and these inadequacies can "constitute a serious threat"--indeed, deadly threat-- "to the public interest, safety, or welfare" of Illinois citizens." Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Notably absent from these proposed rules is a requirement for the testing of "produced water", the fluid that returns from the well during the later stage of production (after flowback). Under the proposed rules, "produced water" can be stored on site and/or can be "recycled", yet there is no testing requirement. Naturally occurring radioactive material (NORM) is found in "produced water" also. See Technologically enhanced naturally occurring radioactive materials in the oil industry (TENORM), Nukleonika 2009; 54(1):3-9, and sources cited therein, especially for TENORM in produced water in the U.S., available at [http://www.nukleonika.pl/www/back/full/vol54\\_2009/v54n1p003f.pdf](http://www.nukleonika.pl/www/back/full/vol54_2009/v54n1p003f.pdf). See also NORM is also found on scale in oil pipes and on fracking equipment. (See Kentucky Resources Council Proposes Comprehensive Plan For Investigating Radiological Contamination In Martha Oil Field. August 11, 2005. <http://www.kyrc.org/webnewspro/112381723236086.shtml>.) IDNR's definitions of "flowback water" and "produced water" are different. The two are distinguishably different enough that they are treated as separate types of fluid by both the Hydraulic Fracturing Regulatory Act and by the DNR Rules. Discharge of produced water onto the ground or into surface water or water drainage way is prohibited but it is not tested for radioactivity. This despite the fact that this fluid will be in contact with the naturally occurring radioactive elements in the ground for a longer period than the flowback and that it is much more likely to be radioactive. Problems: Failure to test produced water for radioactivity is problematic for a variety of reasons including: The health and safety of workers on the site who will be unaware of the levels of radioactivity they are being exposed to. The health and safety of workers transporting produced water who will also be in the dark regarding the levels of radioactivity they will be exposed to. The risk of storing radioactive material in tanks not created for storing radioactive materials. The risk of "recycling" produced water—radioactivity cannot be removed by recycling. The risk to the public in transporting radioactive materials Argonne National Laboratory recently cautioned about radiological doses: "It is commonly accepted that efforts should be undertaken at all times to keep radiological doses 'as low as reasonably achievable,' which is referred to as the ALARA principle or requirement." DNR adequately protect workers and the general public? Elaboration: IDNR does not define a Fixed Date ( $\pm X$  days) for testing. Day 1, <Hour 1 test results will be orders of magnitude lower than either Day 2 or Day 10 tests results, and Day 10 tests results will be significantly lower than Day 80 ( $\pm 7$  days) results. Failure to specify a Fixed Test Date ( $\pm X$  days) renders test data so many irrelevant apples and oranges and allows companies to report suppressed, meaningless results by reporting Day 1, < 1 Hour data. The figure below, provided by the USGS, illustrates the nature of the problem. Please note that radium is not tested at Day 1, < 1 Hour. However, radium coprecipitates with barium, which is represented in total dissolved solids (TDS). It will therefore track TDS fairly closely. Conclusion: companies will be testing the very first flowback water to emerge from a fracked well. It will be Day 1, Minute 1 test results. 2.) There are two pits on a frack pad, one for "emergency" flowback and another, smaller one for drill cuttings and drilling mud. It is a basic principle in horizontal fracking to steer the drill bit through the horizontal strata with the highest gamma radiation readings (GAPI logs). The reason is that radioactivity correlates highly with total organic content (TOC) in the rock, and TOC correlates highly with oil and gas yields. This means that rock cuttings in the smaller drill mud and cuttings frack pit will often be more radioactive than flowback water. The IDNR knows this; yet it does not call for testing of drill bit pits as allowed under the Powers and duties section of the Act (§1- 15). 3.) The term "adjacent to" requires a "precise, clear standard" [IAPA, §100/5-20]. None is given. Does "adjacent to" mean 6 inches, 16 inches, 6 feet, 16 feet, or 60 feet? The IDNR does not say. 4.) Frack pad pipes and equipment can become incredibly radioactive over time. The very large temperature and pressure drops, as fluids move to the surface from thousands of feet underground, means that aqueous radioactive salts precipitate out as scale on pipes and equipment. The levels of radioactivity in pipe scale can exceed 100,000 picoCuries per gram and constitute a hazard to workers, or others who are exposed to recycled scrap metal from gas and oil operations. Yet, IDNR does not call on its General Assembly deferred "Power and authority" [Act, §1-15(e)] to test pipe, tanks, sludge, and equipment. This issue has been an issue in the oil and gas industry since the 1980s. Consequences: According to studies by the Illinois State Geological Survey, the Illinois New Albany Shale Formation, the source rock for our oil and gas reserves, has above average levels of uranium (29 ppm). Uranium decays into radium and thence radon. Both uranium and radium are water soluble. As noted, the U.S. Geological Survey has found oil field brine or produced water in Southern Illinois to have Radium226 levels that average more than 1,000 picoCuries / liter (USGS 1999). That reading is 67 times above the maximum contamination level of the EPA. Radium226 has a half life of 1,600 years. Uranium228 has a half life of 4.468 billion years. If these water soluble salts leach into our aquifers, nearby communities will require--if possible--very expensive water treatment for the next 1,000 years. We may have to return to rainwater harvesting with the modern equivalent of cisterns. The radioactive levels for produced water from shale gas operations are likely to be 2 to 4 times higher than oilfield brine -- on average, 2,000 to 4,000 picoCuries per liter. In addition, radon levels in methane, propane, and ethane can be dangerously high. When it becomes commercial to extract shale gas from the SE corner of the state, major markets, such as Springfield and Chicago, will only be 0.9 and 1.4 days removed from shale gas wellheads. Even though radon222 has a half life of only 3.8 days, the closeness of major Illinois retail gas markets will mean that large number of people will be breathing in high levels of radon when they cook meals. The average level of indoor exposure to radon in Illinois is already 4.4

## Fair Economy Illinois

---

pCi/L ( American Lung Association 2013). The EPA maximum level--the point at which corrective action should be taken--is 4.0 pCi/L, and the preferred level is =3.0 pCi/L. The turn to shale gas, with its high levels of radon, will also turn a major Illinois public health problem in the wrong direction. Radioactive scale in pipe and equipment presents another problem; high levels of radioactivity have been found in school playground equipment and bleachers in school sports stadiums in Mississippi and Texas. Do we want untested oil and gas field scrap metal sold into Illinois markets? Do we want our children exposed on a daily basis to radioactive metal? The present rules creates no barriers to such an outcome. The problems cited above are why Illinois, with its large number of nuclear power plants, has a Low-Level Radioactive Waste Management Act. It and OSHA are the applicable State and Federal agencies with respect to the issue of radioactive waste and work safety standards in settings with exposure to radioactivity. If we faithfully follow applicable State and federal laws, Illinois can minimize the pernicious problems other states are going to face from the uncontrolled release of radioactive elements into their water and soil and work and non-work settings. We should prevent these problem from the start. Cleanup, after the oil and gas industry is gone, will be dreadfully expensive.. Recommendations: 1. Define the test date as = Day 21, the point at which increases in test results begin to level off. 2. Test for "radioactivity" in (1) flowback/produced water, (2) drill cuttings, soil "adjacent to" (3) storage tanks and (4) reserve pits, and (5) pipes and well pad equipment. 3. Define "adjacent to" as between 6 and 12 inches with test samples to be taken within the top 6 inches of soil 4. The rules should also require that the requirements of the Illinois Low Level Radioactivity Waste Management Act be followed.

Sincerely, Lexington Lawson Chicago, IL 60640

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Act §1-75(a)7 requires radioactivity testing "once per well site" for (1) flowback water and ground "adjacent to" (2) storage tanks and (3) reserve pits. Act § 1-120 requires IDNR compliance with all "applicable federal, State, and local laws." One applicable State law is the Illinois Low-Level Radioactive Waste Management Act (PA 83-991 / 420ILCS20). Another is the Occupational Health and Safety Administration (OSHA) standards for workplace safety in settings with exposure to radioactivity (29 CFR 1910.1096). Rules §245.850(d)1-E and §245.850(e) are incomplete and deficient, and these inadequacies can "constitute a serious threat"--indeed, deadly threat-- "to the public interest, safety, or welfare" of Illinois citizens." Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Notably absent from these proposed rules is a requirement for the testing of "produced water", the fluid that returns from the well during the later stage of production (after flowback). Under the proposed rules, "produced water" can be stored on site and/or can be "recycled", yet there is no testing requirement. Naturally occurring radioactive material (NORM) is found in "produced water" also. See Technologically enhanced naturally occurring radioactive materials in the oil industry (TENORM), Nukleonika 2009; 54(1):3-9, and sources cited therein, especially for TENORM in produced water in the U.S., available at [http://www.nukleonika.pl/www/back/full/vol54\\_2009/v54n1p003f.pdf](http://www.nukleonika.pl/www/back/full/vol54_2009/v54n1p003f.pdf). See also NORM is also found on scale in oil pipes and on fracking equipment. (See Kentucky Resources Council Proposes Comprehensive Plan For Investigating Radiological Contamination In Martha Oil Field. August 11, 2005. <http://www.kyrc.org/webnewspro/112381723236086.shtml>.) IDNR's definitions of "flowback water" and "produced water" are different. The two are distinguishably different enough that they are treated as separate types of fluid by both the Hydraulic Fracturing Regulatory Act and by the DNR Rules. Discharge of produced water onto the ground or into surface water or water drainage way is prohibited but it is not tested for radioactivity. This despite the fact that this fluid will be in contact with the naturally occurring radioactive elements in the ground for a longer period than the flowback and that it is much more likely to be radioactive. Problems: Failure to test produced water for radioactivity is problematic for a variety of reasons including: The health and safety of workers on the site who will be unaware of the levels of radioactivity they are being exposed to. The health and safety of workers transporting produced water who will also be in the dark regarding the levels of radioactivity they will be exposed to. The risk of storing radioactive material in tanks not created for storing radioactive materials. The risk of "recycling" produced water—radioactivity cannot be removed by recycling. The risk to the public in transporting radioactive materials Argonne National Laboratory recently cautioned about radiological doses: "It is commonly accepted that efforts should be undertaken at all times to keep radiological doses 'as low as reasonably achievable,' which is referred to as the ALARA principle or requirement." Overview of Radiological Dose and Risk Assessment (April 2011). DNR is failing to even adequately test for radioactivity and therefore, will not know the levels of radioactivity. How, then, can

## Fair Economy Illinois

---

DNR adequately protect workers and the general public? Elaboration: IDNR does not define a Fixed Date ( $\pm X$  days) for testing. Day 1, <Hour 1 test results will be orders of magnitude lower than either Day 2 or Day 10 tests results, and Day 10 tests results will be significantly lower than Day 80 ( $\pm 7$  days) results. Failure to specify a Fixed Test Date ( $\pm X$  days) renders test data so many irrelevant apples and oranges and allows companies to report suppressed, meaningless results by reporting Day 1, < 1 Hour data. The figure below, provided by the USGS, illustrates the nature of the problem. Please note that radium is not tested at Day 1, < 1 Hour. However, radium coprecipitates with barium, which is represented in total dissolved solids (TDS). It will therefore track TDS fairly closely. Conclusion: companies will be testing the very first flowback water to emerge from a fracked well. It will be Day 1, Minute 1 test results. 2.) There are two pits on a frack pad, one for "emergency" flowback and another, smaller one for drill cuttings and drilling mud. It is a basic principle in horizontal fracking to steer the drill bit through the horizontal strata with the highest gamma radiation readings (GAPI logs). The reason is that radioactivity correlates highly with total organic content (TOC) in the rock, and TOC correlates highly with oil and gas yields. This means that rock cuttings in the smaller drill mud and cuttings frack pit will often be more radioactive than flowback water. The IDNR knows this; yet it does not call for testing of drill bit pits as allowed under the Powers and duties section of the Act (§1- 15). 3.) The term "adjacent to" requires a "precise, clear standard" [IAPA, §100/5-20]. None is given. Does "adjacent to" mean 6 inches, 16 inches, 6 feet, 16 feet, or 60 feet? The IDNR does not say. 4.) Frack pad pipes and equipment can become incredibly radioactive over time. The very large temperature and pressure drops, as fluids move to the surface from thousands of feet underground, means that aqueous radioactive salts precipitate out as scale on pipes and equipment. The levels of radioactivity in pipe scale can exceed 100,000 picoCuries per gram and constitute a hazard to workers, or others who are exposed to recycled scrap metal from gas and oil operations. Yet, IDNR does not call on its General Assembly deferred "Power and authority" [Act, §1-15(e)] to test pipe, tanks, sludge, and equipment. This issue has been an issue in the oil and gas industry since the 1980s. Consequences: According to studies by the Illinois State Geological Survey, the Illinois New Albany Shale Formation, the source rock for our oil and gas reserves, has above average levels of uranium (29 ppm). In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Act §1-75(a)7 requires radioactivity testing "once per well site" for (1) flowback water and ground "adjacent to" (2) storage tanks and (3) reserve pits. Act § 1-120 requires IDNR compliance with all "applicable federal, State, and local laws." One applicable State law is the Illinois Low-Level Radioactive Waste Management Act (PA 83-991 / 420ILCS20). Another is the Occupational Health and Safety Administration (OSHA) standards for workplace safety in settings with exposure to radioactivity (29 CFR 1910.1096). Rules §245.850(d)1-E and §245.850(e) are incomplete and deficient, and these inadequacies can "constitute a serious threat"--indeed, deadly threat-- "to the public interest, safety, or welfare" of Illinois citizens." Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Notably absent from these proposed rules is a requirement for the testing of "produced water", the fluid that returns from the well during the later stage of production (after flowback). Under the proposed rules, "produced water" can be stored on site and/or can be "recycled", yet there is no testing requirement. Naturally occurring radioactive material (NORM) is found in "produced water" also. See Technologically enhanced naturally occurring radioactive materials in the oil industry (TENORM), Nukleonika 2009; 54(1):3-9, and sources cited therein, especially for TENORM in produced water in the U.S., available at [http://www.nukleonika.pl/www/back/full/vol54\\_2009/v54n1p003f.pdf](http://www.nukleonika.pl/www/back/full/vol54_2009/v54n1p003f.pdf). See also NORM is also found on scale in oil pipes and on fracking equipment. (See Kentucky Resources Council Proposes Comprehensive Plan For Investigating Radiological Contamination In Martha Oil Field. August 11, 2005. <http://www.kyrc.org/webnewspro/112381723236086.shtml>.) IDNR's definitions of "flowback water" and "produced water" are different. The two are distinguishably different enough that they are treated as separate types of fluid by both the Hydraulic Fracturing Regulatory Act and by the DNR Rules. Discharge of produced water onto the ground or into surface water or water drainage way is prohibited but it is not tested for radioactivity. This despite the fact that this fluid will be in contact with the naturally occurring radioactive elements in the ground for a longer period than the flowback and that it is much more likely to be radioactive. Problems: Failure to test produced water for radioactivity is problematic for a variety of reasons including: The health and safety of workers on the site who will be unaware of the levels of radioactivity they are being exposed to. The health and safety of workers transporting produced water who will also be in the dark regarding the levels of radioactivity they will be exposed to. The risk of storing radioactive material in tanks not created for storing radioactive materials. The risk of "recycling" produced water—radioactivity cannot be removed by recycling. The risk to the public in transporting radioactive materials Argonne National Laboratory recently cautioned about radiological doses: "It is commonly accepted that efforts should be undertaken at all times to keep radiological doses 'as low as reasonably achievable,' which is referred to as the ALARA principle or requirement." Overview of Radiological Dose and Risk Assessment (April 2011). DNR is failing to even adequately test for radioactivity and therefore, will not know the levels of radioactivity. How, then, can

## Fair Economy Illinois

---

DNR adequately protect workers and the general public? Elaboration: IDNR does not define a Fixed Date ( $\pm X$  days) for testing. Day 1, <Hour 1 test results will be orders of magnitude lower than either Day 2 or Day 10 tests results, and Day 10 tests results will be significantly lower than Day 80 ( $\pm 7$  days) results. Failure to specify a Fixed Test Date ( $\pm X$  days) renders test data so many irrelevant apples and oranges and allows companies to report suppressed, meaningless results by reporting Day 1, < 1 Hour data. The figure below, provided by the USGS, illustrates the nature of the problem. Please note that radium is not tested at Day 1, < 1 Hour. However, radium coprecipitates with barium, which is represented in total dissolved solids (TDS). It will therefore track TDS fairly closely. Conclusion: companies will be testing the very first flowback water to emerge from a fracked well. It will be Day 1, Minute 1 test results. 2.) There are two pits on a frack pad, one for "emergency" flowback and another, smaller one for drill cuttings and drilling mud. It is a basic principle in horizontal fracking to steer the drill bit through the horizontal strata with the highest gamma radiation readings (GAPI logs). The reason is that radioactivity correlates highly with total organic content (TOC) in the rock, and TOC correlates highly with oil and gas yields. This means that rock cuttings in the smaller drill mud and cuttings frack pit will often be more radioactive than flowback water. The IDNR knows this; yet it does not call for testing of drill bit pits as allowed under the Powers and duties section of the Act (§1- 15). 3.) The term "adjacent to" requires a "precise, clear standard" [IAPA, §100/5-20]. None is given. Does "adjacent to" mean 6 inches, 16 inches, 6 feet, 16 feet, or 60 feet? The IDNR does not say. 4.) Frack pad pipes and equipment can become incredibly radioactive over time. The very large temperature and pressure drops, as fluids move to the surface from thousands of feet underground, means that aqueous radioactive salts precipitate out as scale on pipes and equipment. The levels of radioactivity in pipe scale can exceed 100,000 picoCuries per gram and constitute a hazard to workers, or others who are exposed to recycled scrap metal from gas and oil operations. Yet, IDNR does not call on its General Assembly deferred "Power and authority" [Act, §1-15(e)] to test pipe, tanks, sludge, and equipment. This issue has been an issue in the oil and gas industry since the 1980s. Consequences: According to studies by the Illinois State Geological Survey, the Illinois New Albany Shale Formation, the source rock for our oil and gas reserves, has above average levels of uranium (29 ppm). Uranium decays into radium and thence radon. Both uranium and radium are water soluble. As noted, the U.S. Geological Survey has found oil field brine or produced water in Southern Illinois to have Radium226 levels that average more than 1,000 picoCuries / liter (USGS 1999). That reading is 67 times above the maximum contamination level of the EPA. Radium226 has a half life of 1,600 years. Uranium228 has a half life of 4.468 billion years. If these water soluble salts leach into our aquifers, nearby communities will require--if possible--very expensive water treatment for the next 1,000 years. We may have to return to rainwater harvesting with the modern equivalent of cisterns. The radioactive levels for produced water from shale gas operations are likely to be 2 to 4 times higher than oilfield brine -- on average, 2,000 to 4,000 picoCuries per liter. In addition, radon levels in methane, propane, and ethane can be dangerously high. When it becomes commercial to extract shale gas from the SE corner of the state, major markets, such as Springfield and Chicago, will only be 0.9 and 1.4 days removed from shale gas wellheads. Even though radon222 has a half life of only 3.8 days, the closeness of major Illinois retail gas markets will mean that large number of people will be breathing in high levels of radon when they cook meals. The average level of indoor exposure to radon in Illinois is already 4.4

## Fair Economy Illinois

---

pCi/L ( American Lung Association 2013). The EPA maximum level--the point at which corrective action should be taken--is 4.0 pCi/L, and the preferred level is =3.0 pCi/L. The turn to shale gas, with its high levels of radon, will also turn a major Illinois public health problem in the wrong direction. Radioactive scale in pipe and equipment presents another problem; high levels of radioactivity have been found in school playground equipment and bleachers in school sports stadiums in Mississippi and Texas. Do we want untested oil and gas field scrap metal sold into Illinois markets? Do we want our children exposed on a daily basis to radioactive metal? The present rules creates no barriers to such an outcome. The problems cited above are why Illinois, with its large number of nuclear power plants, has a Low-Level Radioactive Waste Management Act. It and OSHA are the applicable State and Federal agencies with respect to the issue of radioactive waste and work safety standards in settings with exposure to radioactivity. If we faithfully follow applicable State and federal laws, Illinois can minimize the pernicious problems other states are going to face from the uncontrolled release of radioactive elements into their water and soil and work and non-work settings. We should prevent these problem from the start. Cleanup, after the oil and gas industry is gone, will be dreadfully expensive.. Recommendations: 1. Define the test date as = Day 21, the point at which increases in test results begin to level off. 2. Test for "radioactivity" in (1) flowback/produced water, (2) drill cuttings, soil "adjacent to" (3) storage tanks and (4) reserve pits, and (5) pipes and well pad equipment. 3. Define "adjacent to" as between 6 and 12 inches with test samples to be taken within the top 6 inches of soil 4. The rules should also require that the requirements of the Illinois Low Level Radioactivity Waste Management Act be followed.

Sincerely, Lupita Carrasquillo Chicago, IL 60605

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Act §1-75(a)7 requires radioactivity testing "once per well site" for (1) flowback water and ground "adjacent to" (2) storage tanks and (3) reserve pits. Act § 1-120 requires IDNR compliance with all "applicable federal, State, and local laws." One applicable State law is the Illinois Low-Level Radioactive Waste Management Act (PA 83-991 / 420ILCS20). Another is the Occupational Health and Safety Administration (OSHA) standards for workplace safety in settings with exposure to radioactivity (29 CFR 1910.1096). Rules §245.850(d)1-E and §245.850(e) are incomplete and deficient, and these inadequacies can "constitute a serious threat"--indeed, deadly threat-- "to the public interest, safety, or welfare" of Illinois citizens." Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Notably absent from these proposed rules is a requirement for the testing of "produced water", the fluid that returns from the well during the later stage of production (after flowback). Under the proposed rules, "produced water" can be stored on site and/or can be "recycled", yet there is no testing requirement. Naturally occurring radioactive material (NORM) is found in "produced water" also. See Technologically enhanced naturally occurring radioactive materials in the oil industry (TENORM), Nukleonika 2009; 54(1):3-9, and sources cited therein, especially for TENORM in produced water in the U.S., available at [http://www.nukleonika.pl/www/back/full/vol54\\_2009/v54n1p003f.pdf](http://www.nukleonika.pl/www/back/full/vol54_2009/v54n1p003f.pdf). See also NORM is also found on scale in oil pipes and on fracking equipment. (See Kentucky Resources Council Proposes Comprehensive Plan For Investigating Radiological Contamination In Martha Oil Field. August 11, 2005. <http://www.kyrc.org/webnewspro/112381723236086.shtml>.) IDNR's definitions of "flowback water" and "produced water" are different. The two are distinguishably different enough that they are treated as separate types of fluid by both the Hydraulic Fracturing Regulatory Act and by the DNR Rules. Discharge of produced water onto the ground or into surface water or water drainage way is prohibited but it is not tested for radioactivity. This despite the fact that this fluid will be in contact with the naturally occurring radioactive elements in the ground for a longer period than the flowback and that it is much more likely to be radioactive. Problems: Failure to test produced water for radioactivity is problematic for a variety of reasons including: The health and safety of workers on the site who will be unaware of the levels of radioactivity they are being exposed to. The health and safety of workers transporting produced water who will also be in the dark regarding the levels of radioactivity they will be exposed to. The risk of storing radioactive material in tanks not created for storing radioactive materials. The risk of "recycling" produced water—radioactivity cannot be removed by recycling. The risk to the public in transporting radioactive materials Argonne National Laboratory recently cautioned about radiological doses: "It is commonly accepted that efforts should be undertaken at all times to keep radiological doses 'as low as reasonably achievable,' which is referred to as the ALARA principle or requirement." Overview of Radiological Dose and Risk Assessment (April 2011). DNR is failing to even adequately test for radioactivity and therefore, will not know the levels of radioactivity. How, then, can

## Fair Economy Illinois

---

DNR adequately protect workers and the general public? Elaboration: IDNR does not define a Fixed Date ( $\pm X$  days) for testing. Day 1, <Hour 1 test results will be orders of magnitude lower than either Day 2 or Day 10 tests results, and Day 10 tests results will be significantly lower than Day 80 ( $\pm 7$  days) results. Failure to specify a Fixed Test Date ( $\pm X$  days) renders test data so many irrelevant apples and oranges and allows companies to report suppressed, meaningless results by reporting Day 1, < 1 Hour data. The figure below, provided by the USGS, illustrates the nature of the problem. Please note that radium is not tested at Day 1, < 1 Hour. However, radium coprecipitates with barium, which is represented in total dissolved solids (TDS). It will therefore track TDS fairly closely. Conclusion: companies will be testing the very first flowback water to emerge from a fracked well. It will be Day 1, Minute 1 test results. 2.) There are two pits on a frack pad, one for "emergency" flowback and another, smaller one for drill cuttings and drilling mud. It is a basic principle in horizontal fracking to steer the drill bit through the horizontal strata with the highest gamma radiation readings (GAPI logs). The reason is that radioactivity correlates highly with total organic content (TOC) in the rock, and TOC correlates highly with oil and gas yields. This means that rock cuttings in the smaller drill mud and cuttings frack pit will often be more radioactive than flowback water. The IDNR knows this; yet it does not call for testing of drill bit pits as allowed under the Powers and duties section of the Act (§1- 15). 3.) The term "adjacent to" requires a "precise, clear standard" [IAPA, §100/5-20]. None is given. Does "adjacent to" mean 6 inches, 16 inches, 6 feet, 16 feet, or 60 feet? The IDNR does not say. 4.) Frack pad pipes and equipment can become incredibly radioactive over time. The very large temperature and pressure drops, as fluids move to the surface from thousands of feet underground, means that aqueous radioactive salts precipitate out as scale on pipes and equipment. The levels of radioactivity in pipe scale can exceed 100,000 picoCuries per gram and constitute a hazard to workers, or others who are exposed to recycled scrap metal from gas and oil operations. Yet, IDNR does not call on its General Assembly deferred "Power and authority" [Act, §1-15(e)] to test pipe, tanks, sludge, and equipment. This issue has been an issue in the oil and gas industry since the 1980s. Consequences: According to studies by the Illinois State Geological Survey, the Illinois New Albany Shale Formation, the source rock for our oil and gas reserves, has above average levels of uranium (29 ppm). Uranium decays into radium and thence radon. Both uranium and radium are water soluble. As noted, the U.S. Geological Survey has found oil field brine or produced water in Southern Illinois to have Radium226 levels that average more than 1,000 picoCuries / liter (USGS 1999). That reading is 67 times above the maximum contamination level of the EPA. Radium226 has a half life of 1,600 years. Uranium228 has a half life of 4.468 billion years. If these water soluble salts leach into our aquifers, nearby communities will require--if possible--very expensive water treatment for the next 1,000 years. We may have to return to rainwater harvesting with the modern equivalent of cisterns. The radioactive levels for produced water from shale gas operations are likely to be 2 to 4 times higher than oilfield brine -- on average, 2,000 to 4,000 picoCuries per liter. In addition, radon levels in methane, propane, and ethane can be dangerously high. When it becomes commercial to extract shale gas from the SE corner of the state, major markets, such as Springfield and Chicago, will only be 0.9 and 1.4 days removed from shale gas wellheads. Even though radon222 has a half life of only 3.8 days, the closeness of major Illinois retail gas markets will mean that large number of people will be breathing in high levels of radon when they cook meals. The average level of indoor exposure to radon in Illinois is already 4.4

## Fair Economy Illinois

---

pCi/L ( American Lung Association 2013). The EPA maximum level--the point at which corrective action should be taken--is 4.0 pCi/L, and the preferred level is =3.0 pCi/L. The turn to shale gas, with its high levels of radon, will also turn a major Illinois public health problem in the wrong direction. Radioactive scale in pipe and equipment presents another problem; high levels of radioactivity have been found in school playground equipment and bleachers in school sports stadiums in Mississippi and Texas. Do we want untested oil and gas field scrap metal sold into Illinois markets? Do we want our children exposed on a daily basis to radioactive metal? The present rules creates no barriers to such an outcome. The problems cited above are why Illinois, with its large number of nuclear power plants, has a Low-Level Radioactive Waste Management Act. It and OSHA are the applicable State and Federal agencies with respect to the issue of radioactive waste and work safety standards in settings with exposure to radioactivity. If we faithfully follow applicable State and federal laws, Illinois can minimize the pernicious problems other states are going to face from the uncontrolled release of radioactive elements into their water and soil and work and non-work settings. We should prevent these problem from the start. Cleanup, after the oil and gas industry is gone, will be dreadfully expensive.. Recommendations: 1. Define the test date as = Day 21, the point at which increases in test results begin to level off. 2. Test for "radioactivity" in (1) flowback/produced water, (2) drill cuttings, soil "adjacent to" (3) storage tanks and (4) reserve pits, and (5) pipes and well pad equipment. 3. Define "adjacent to" as between 6 and 12 inches with test samples to be taken within the top 6 inches of soil 4. The rules should also require that the requirements of the Illinois Low Level Radioactivity Waste Management Act be followed.

Sincerely, Madeline McCann Chicago, IL 60637

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Act §1-75(a)7 requires radioactivity testing "once per well site" for (1) flowback water and ground "adjacent to" (2) storage tanks and (3) reserve pits. Act § 1-120 requires IDNR compliance with all "applicable federal, State, and local laws." One applicable State law is the Illinois Low-Level Radioactive Waste Management Act (PA 83-991 / 420ILCS20). Another is the Occupational Health and Safety Administration (OSHA) standards for workplace safety in settings with exposure to radioactivity (29 CFR 1910.1096). Rules §245.850(d)1-E and §245.850(e) are incomplete and deficient, and these inadequacies can "constitute a serious threat"--indeed, deadly threat-- "to the public interest, safety, or welfare" of Illinois citizens." Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Notably absent from these proposed rules is a requirement for the testing of "produced water", the fluid that returns from the well during the later stage of production (after flowback). Under the proposed rules, "produced water" can be stored on site and/or can be "recycled", yet there is no testing requirement. Naturally occurring radioactive material (NORM) is found in "produced water" also. See Technologically enhanced naturally occurring radioactive materials in the oil industry (TENORM), Nukleonika 2009; 54(1):3-9, and sources cited therein, especially for TENORM in produced water in the U.S., available at [http://www.nukleonika.pl/www/back/full/vol54\\_2009/v54n1p003f.pdf](http://www.nukleonika.pl/www/back/full/vol54_2009/v54n1p003f.pdf). See also NORM is also found on scale in oil pipes and on fracking equipment. (See Kentucky Resources Council Proposes Comprehensive Plan For Investigating Radiological Contamination In Martha Oil Field. August 11, 2005. <http://www.kyrc.org/webnewspro/112381723236086.shtml>.) IDNR's definitions of "flowback water" and "produced water" are different. The two are distinguishably different enough that they are treated as separate types of fluid by both the Hydraulic Fracturing Regulatory Act and by the DNR Rules. Discharge of produced water onto the ground or into surface water or water drainage way is prohibited but it is not tested for radioactivity. It is a basic principle in horizontal fracking to steer the drill bit through the horizontal strata with the highest gamma radiation readings (GAPI logs). The reason is that radioactivity correlates highly with total organic content (TOC) in the rock, and TOC correlates highly with oil and gas yields. This means that rock cuttings in the smaller drill mud and cuttings frack pit will often be more radioactive than flowback water. The IDNR knows this; yet it does not call for testing of drill bit pits as allowed under the Powers and duties section of the Act (§1- 15). 3.) The term "adjacent to" requires a "precise, clear standard" [IAPA, §100/5-20]. None is given. Does "adjacent to" mean 6 inches, 16 inches, 6 feet, 16 feet, or 60 feet? The IDNR does not say. 4.) Frack pad pipes and equipment can become incredibly radioactive over time. The very large temperature and pressure drops, as fluids move to the surface from thousands of feet underground, means that aqueous radioactive salts precipitate out as scale on pipes and equipment. The levels of radioactivity in pipe scale can exceed 100,000 picoCuries per gram and constitute a hazard to workers, or others who are exposed to recycled scrap metal from gas and oil operations. Yet, IDNR does not call on its General Assembly deferred "Power and authority" [Act, §1-15(e)] to test pipe, tanks, sludge, and equipment. This issue has been an issue in the oil and gas industry since the 1980s. Consequences: According to studies by the Illinois State Geological Survey, the Illinois New Albany Shale Formation, the source rock for our oil and gas reserves, has above average levels of uranium (29 ppm). Uranium decays into radium and thence radon. Both uranium and radium are water soluble. As noted, the U.S. Geological Survey has found oil field brine or produced water in Southern Illinois to have Radium226 levels that average more than 1,000 picoCuries / liter (USGS 1999). That reading is 67 times above the maximum contamination level of the EPA. Radium226 has a half life of 1,600 years. Uranium228 has a half life of 4.468 billion years. If these water soluble salts leach into our aquifers, nearby communities will require--if possible--very expensive water treatment for the next 1,000 years. We may have to return to rainwater harvesting with the modern equivalent of cisterns. The radioactive levels for produced water from shale gas operations are likely to be 2 to 4 times higher than oilfield brine -- on average, 2,000 to 4,000 picoCuries per liter. In addition, radon levels in methane, propane, and ethane can be dangerously high. When it becomes commercial to extract shale gas from the SE corner of the state, major markets, such as Springfield and Chicago, will only be 0.9 and 1.4 days removed from shale gas wellheads. Even though radon222 has a half life of only 3.8 days, the closeness of major Illinois retail gas markets will mean that large number of people will be breathing in high levels of radon when they cook meals. The average level of indoor exposure to radon in Illinois is already 4.4

## Fair Economy Illinois

---

pCi/L ( American Lung Association 2013). The EPA maximum level--the point at which corrective action should be taken--is 4.0 pCi/L, and the preferred level is =3.0 pCi/L. The turn to shale gas, with its high levels of radon, will also turn a major Illinois public health problem in the wrong direction. Radioactive scale in pipe and equipment presents another problem; high levels of radioactivity have been found in school playground equipment and bleachers in school sports stadiums in Mississippi and Texas. Do we want untested oil and gas field scrap metal sold into Illinois markets? Do we want our children exposed on a daily basis to radioactive metal? The present rules creates no barriers to such an outcome. The problems cited above are why Illinois, with its large number of nuclear power plants, has a Low-Level Radioactive Waste Management Act. It and OSHA are the applicable State and Federal agencies with respect to the issue of radioactive waste and work safety standards in settings with exposure to radioactivity. If we faithfully follow applicable State and federal laws, Illinois can minimize the pernicious problems other states are going to face from the uncontrolled release of radioactive elements into their water and soil and work and non-work settings. We should prevent these problem from the start. Cleanup, after the oil and gas industry is gone, will be dreadfully expensive.. Recommendations: 1. Define the test date as = Day 21, the point at which increases in test results begin to level off. 2. Test for "radioactivity" in (1) flowback/produced water, (2) drill cuttings, soil "adjacent to" (3) storage tanks and (4) reserve pits, and (5) pipes and well pad equipment. 3. Define "adjacent to" as between 6 and 12 inches with test samples to be taken within the top 6 inches of soil 4. The rules should also require that the requirements of the Illinois Low Level Radioactivity Waste Management Act be followed.

Sincerely, Maryann Condren Naperville, IL 60540

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Act §1-75(a)7 requires radioactivity testing "once per well site" for (1) flowback water and ground "adjacent to" (2) storage tanks and (3) reserve pits. Act § 1-120 requires IDNR compliance with all "applicable federal, State, and local laws." One applicable State law is the Illinois Low-Level Radioactive Waste Management Act (PA 83-991 / 420ILCS20). Another is the Occupational Health and Safety Administration (OSHA) standards for workplace safety in settings with exposure to radioactivity (29 CFR 1910.1096). Rules §245.850(d)1-E and §245.850(e) are incomplete and deficient, and these inadequacies can "constitute a serious threat"--indeed, deadly threat-- "to the public interest, safety, or welfare" of Illinois citizens." Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Notably absent from these proposed rules is a requirement for the testing of "produced water", the fluid that returns from the well during the later stage of production (after flowback). Under the proposed rules, "produced water" can be stored on site and/or can be "recycled", yet there is no testing requirement. Naturally occurring radioactive material (NORM) is found in "produced water" also. See Technologically enhanced naturally occurring radioactive materials in the oil industry (TENORM), Nukleonika 2009; 54(1):3-9, and sources cited therein, especially for TENORM in produced water in the U.S., available at [http://www.nukleonika.pl/www/back/full/vol54\\_2009/v54n1p003f.pdf](http://www.nukleonika.pl/www/back/full/vol54_2009/v54n1p003f.pdf). See also NORM is also found on scale in oil pipes and on fracking equipment. (See Kentucky Resources Council Proposes Comprehensive Plan For Investigating Radiological Contamination In Martha Oil Field. August 11, 2005. <http://www.kyrc.org/webnewspro/112381723236086.shtml>.) IDNR's definitions of "flowback water" and "produced water" are different. The two are distinguishably different enough that they are treated as separate types of fluid by both the Hydraulic Fracturing Regulatory Act and by the DNR Rules. Discharge of produced water onto the ground or into surface water or water drainage way is prohibited but it is not tested for radioactivity. This despite the fact that this fluid will be in contact with the naturally occurring radioactive elements in the ground for a longer period than the flowback and that it is much more likely to be radioactive. Problems: Failure to test produced water for radioactivity is problematic for a variety of reasons including: The health and safety of workers on the site who will be unaware of the levels of radioactivity they are being exposed to. The health and safety of workers transporting produced water who will also be in the dark regarding the levels of radioactivity they will be exposed to. The risk of storing radioactive material in tanks not created for storing radioactive materials. The risk of "recycling" produced water—radioactivity cannot be removed by recycling. The risk to the public in transporting radioactive materials Argonne National Laboratory recently cautioned about radiological doses: "It is commonly accepted that efforts should be undertaken at all times to keep radiological doses 'as low as reasonably achievable,' which is referred to as the ALARA principle or requirement." Overview of Radiological Dose and Risk Assessment (April 2011). DNR is failing to even adequately test for radioactivity and therefore, will not know the levels of radioactivity. How, then, can

## Fair Economy Illinois

---

DNR adequately protect workers and the general public? Elaboration: IDNR does not define a Fixed Date ( $\pm X$  days) for testing. Day 1, <Hour 1 test results will be orders of magnitude lower than either Day 2 or Day 10 tests results, and Day 10 tests results will be significantly lower than Day 80 ( $\pm 7$  days) results. Failure to specify a Fixed Test Date ( $\pm X$  days) renders test data so many irrelevant apples and oranges and allows companies to report suppressed, meaningless results by reporting Day 1, < 1 Hour data. The figure below, provided by the USGS, illustrates the nature of the problem. Please note that radium is not tested at Day 1, < 1 Hour. However, radium coprecipitates with barium, which is represented in total dissolved solids (TDS). It will therefore track TDS fairly closely. Conclusion: companies will be testing the very first flowback water to emerge from a fracked well. It will be Day 1, Minute 1 test results. 2.) There are two pits on a frack pad, one for "emergency" flowback and another, smaller one for drill cuttings and drilling mud. It is a basic principle in horizontal fracking to steer the drill bit through the horizontal strata with the highest gamma radiation readings (GAPI logs). The reason is that radioactivity correlates highly with total organic content (TOC) in the rock, and TOC correlates highly with oil and gas yields. This means that rock cuttings in the smaller drill mud and cuttings frack pit will often be more radioactive than flowback water. The IDNR knows this; yet it does not call for testing of drill bit pits as allowed under the Powers and duties section of the Act (§1- 15). 3.) The term "adjacent to" requires a "precise, clear standard" [IAPA, §100/5-20]. None is given. Does "adjacent to" mean 6 inches, 16 inches, 6 feet, 16 feet, or 60 feet? The IDNR does not say. 4.) Frack pad pipes and equipment can become incredibly radioactive over time. The very large temperature and pressure drops, as fluids move to the surface from thousands of feet underground, means that aqueous radioactive salts precipitate out as scale on pipes and equipment. pCi/L ( American Lung Association 2013). The EPA maximum level--the point at which corrective action should be taken--is 4.0 pCi/L, and the preferred level is =3.0 pCi/L. The turn to shale gas, with its high levels of radon, will also turn a major Illinois public health problem in the wrong direction. Radioactive scale in pipe and equipment presents another problem; high levels of radioactivity have been found in school playground equipment and bleachers in school sports stadiums in Mississippi and Texas. Do we want untested oil and gas field scrap metal sold into Illinois markets? Do we want our children exposed on a daily basis to radioactive metal? The present rules creates no barriers to such an outcome. The problems cited above are why Illinois, with its large number of nuclear power plants, has a Low-Level Radioactive Waste Management Act. It and OSHA are the applicable State and Federal agencies with respect to the issue of radioactive waste and work safety standards in settings with exposure to radioactivity. If we faithfully follow applicable State and federal laws, Illinois can minimize the pernicious problems other states are going to face from the uncontrolled release of radioactive elements into their water and soil and work and non-work settings. We should prevent these problem from the start. Cleanup, after the oil and gas industry is gone, will be dreadfully expensive.. Recommendations: 1. Define the test date as = Day 21, the point at which increases in test results begin to level off. 2. Test for "radioactivity" in (1) flowback/produced water, (2) drill cuttings, soil "adjacent to" (3) storage tanks and (4) reserve pits, and (5) pipes and well pad equipment. 3. Define "adjacent to" as between 6 and 12 inches with test samples to be taken within the top 6 inches of soil 4. The rules should also require that the requirements of the Illinois Low Level Radioactivity Waste Management Act be followed.

Sincerely, Matthew Raigosa Chicago, IL 60608

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Act §1-75(a)7 requires radioactivity testing "once per well site" for (1) flowback water and ground "adjacent to" (2) storage tanks and (3) reserve pits. Act § 1-120 requires IDNR compliance with all "applicable federal, State, and local laws." One applicable State law is the Illinois Low-Level Radioactive Waste Management Act (PA 83-991 / 420ILCS20). Another is the Occupational Health and Safety Administration (OSHA) standards for workplace safety in settings with exposure to radioactivity (29 CFR 1910.1096). Rules §245.850(d)1-E and §245.850(e) are incomplete and deficient, and these inadequacies can "constitute a serious threat"--indeed, deadly threat-- "to the public interest, safety, or welfare" of Illinois citizens." Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Notably absent from these proposed rules is a requirement for the testing of "produced water", the fluid that returns from the well during the later stage of production (after flowback). Under the proposed rules, "produced water" can be stored on site and/or can be "recycled", yet there is no testing requirement. Naturally occurring radioactive material (NORM) is found in "produced water" also. See Technologically enhanced naturally occurring radioactive materials in the oil industry (TENORM), Nukleonika 2009; 54(1):3-9, and sources cited therein, especially for TENORM in produced water in the U.S., available at [http://www.nukleonika.pl/www/back/full/vol54\\_2009/v54n1p003f.pdf](http://www.nukleonika.pl/www/back/full/vol54_2009/v54n1p003f.pdf). See also NORM is also found on scale in oil pipes and on fracking equipment. (See Kentucky Resources Council Proposes Comprehensive Plan For Investigating Radiological Contamination In Martha Oil Field. August 11, 2005. <http://www.kyrc.org/webnewspro/112381723236086.shtml>.) IDNR's definitions of "flowback water" and "produced water" are different. The two are distinguishably different enough that they are treated as separate types of fluid by both the Hydraulic Fracturing Regulatory Act and by the DNR Rules. Discharge of produced water onto the ground or into surface water or water drainage way is prohibited but it is not tested for radioactivity. This despite the fact that this fluid will be in contact with the naturally occurring radioactive elements in the ground for a longer period than the flowback and that it is much more likely to be radioactive. Problems: Failure to test produced water for radioactivity is problematic for a variety of reasons including: The health and safety of workers on the site who will be unaware of the levels of radioactivity they are being exposed to. The health and safety of workers transporting produced water who will also be in the dark regarding the levels of radioactivity they will be exposed to. The risk of storing radioactive material in tanks not created for storing radioactive materials. The risk of "recycling" produced water—radioactivity cannot be removed by recycling. The risk to the public in transporting radioactive materials Argonne National Laboratory recently cautioned about radiological doses: "It is commonly accepted that efforts should be undertaken at all times to keep radiological doses 'as low as reasonably achievable,' which is referred to as the ALARA principle or requirement." Overview of Radiological Dose and Risk Assessment (April 2011). DNR is failing to even adequately test for radioactivity and therefore, will not know the levels of radioactivity. How, then, can

## Fair Economy Illinois

---

DNR adequately protect workers and the general public? Elaboration: IDNR does not define a Fixed Date ( $\pm X$  days) for testing. Day 1, <Hour 1 test results will be orders of magnitude lower than either Day 2 or Day 10 tests results, and Day 10 tests results will be significantly lower than Day 80 ( $\pm 7$  days) results. Failure to specify a Fixed Test Date ( $\pm X$  days) renders test data so many irrelevant apples and oranges and allows companies to report suppressed, meaningless results by reporting Day 1, < 1 Hour data. The figure below, provided by the USGS, illustrates the nature of the problem. Please note that radium is not tested at Day 1, < 1 Hour. However, radium coprecipitates with barium, which is represented in total dissolved solids (TDS). It will therefore track TDS fairly closely. Conclusion: companies will be testing the very first flowback water to emerge from a fracked well. It will be Day 1, Minute 1 test results. 2.) There are two pits on a frack pad, one for "emergency" flowback and another, smaller one for drill cuttings and drilling mud. It is a basic principle in horizontal fracking to steer the drill bit through the horizontal strata with the highest gamma radiation readings (GAPI logs). The reason is that radioactivity correlates highly with total organic content (TOC) in the rock, and TOC correlates highly with oil and gas yields. This means that rock cuttings in the smaller drill mud and cuttings frack pit will often be more radioactive than flowback water. The IDNR knows this; yet it does not call for testing of drill bit pits as allowed under the Powers and duties section of the Act (§1- 15). 3.) The term "adjacent to" requires a "precise, clear standard" [IAPA, §100/5-20]. None is given. Does "adjacent to" mean 6 inches, 16 inches, 6 feet, 16 feet, or 60 feet? The IDNR does not say. 4.) Frack pad pipes and equipment can become incredibly radioactive over time. The very large temperature and pressure drops, as fluids move to the surface from thousands of feet underground, means that aqueous radioactive salts precipitate out as scale on pipes and equipment. The levels of radioactivity in pipe scale can exceed 100,000 picoCuries per gram and constitute a hazard to workers, or others who are exposed to recycled scrap metal from gas and oil operations. Yet, IDNR does not call on its General Assembly deferred "Power and authority" [Act, §1-15(e)] to test pipe, tanks, sludge, and equipment. This issue has been an issue in the oil and gas industry since the 1980s. Consequences: According to studies by the Illinois State Geological Survey, the Illinois New Albany Shale Formation, the source rock for our oil and gas reserves, has above average levels of uranium (29 ppm). Uranium decays into radium and thence radon. Both uranium and radium are water soluble. As noted, the U.S. Geological Survey has found oil field brine or produced water in Southern Illinois to have Radium226 levels that average more than 1,000 picoCuries / liter (USGS 1999). That reading is 67 times above the maximum contamination level of the EPA. Radium226 has a half life of 1,600 years. Uranium228 has a half life of 4.468 billion years. If these water soluble salts leach into our aquifers, nearby communities will require--if possible--very expensive water treatment for the next 1,000 years. We may have to return to rainwater harvesting with the modern equivalent of cisterns. The radioactive levels for produced water from shale gas operations are likely to be 2 to 4 times higher than oilfield brine -- on average, 2,000 to 4,000 picoCuries per liter. In addition, radon levels in methane, propane, and ethane can be dangerously high. When it becomes commercial to extract shale gas from the SE corner of the state, major markets, such as Springfield and Chicago, will only be 0.9 and 1.4 days removed from shale gas wellheads. Even though radon222 has a half life of only 3.8 days, the closeness of major Illinois retail gas markets will mean that large number of people will be breathing in high levels of radon when they cook meals. The average level of indoor exposure to radon in Illinois is already 4.4

## Fair Economy Illinois

---

pCi/L ( American Lung Association 2013). The EPA maximum level--the point at which corrective action should be taken--is 4.0 pCi/L, and the preferred level is =3.0 pCi/L. The turn to shale gas, with its high levels of radon, will also turn a major Illinois public health problem in the wrong direction. Radioactive scale in pipe and equipment presents another problem; high levels of radioactivity have been found in school playground equipment and bleachers in school sports stadiums in Mississippi and Texas. Do we want untested oil and gas field scrap metal sold into Illinois markets? Do we want our children exposed on a daily basis to radioactive metal? The present rules creates no barriers to such an outcome. The problems cited above are why Illinois, with its large number of nuclear power plants, has a Low-Level Radioactive Waste Management Act. In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Act §1-75(a)7 requires radioactivity testing "once per well site" for (1) flowback water and ground "adjacent to" (2) storage tanks and (3) reserve pits. Act § 1-120 requires IDNR compliance with all "applicable federal, State, and local laws." One applicable State law is the Illinois Low-Level Radioactive Waste Management Act (PA 83-991 / 420ILCS20). Another is the Occupational Health and Safety Administration (OSHA) standards for workplace safety in settings with exposure to radioactivity (29 CFR 1910.1096). Rules §245.850(d)1-E and §245.850(e) are incomplete and deficient, and these inadequacies can "constitute a serious threat"--indeed, deadly threat-- "to the public interest, safety, or welfare" of Illinois citizens." Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Notably absent from these proposed rules is a requirement for the testing of "produced water", the fluid that returns from the well during the later stage of production (after flowback). Under the proposed rules, "produced water" can be stored on site and/or can be "recycled", yet there is no testing requirement. Naturally occurring radioactive material (NORM) is found in "produced water" also. See Technologically enhanced naturally occurring radioactive materials in the oil industry (TENORM), Nukleonika 2009; 54(1):3-9, and sources cited therein, especially for TENORM in produced water in the U.S., available at [http://www.nukleonika.pl/www/back/full/vol54\\_2009/v54n1p003f.pdf](http://www.nukleonika.pl/www/back/full/vol54_2009/v54n1p003f.pdf). See also NORM is also found on scale in oil pipes and on fracking equipment. (See Kentucky Resources Council Proposes Comprehensive Plan For Investigating Radiological Contamination In Martha Oil Field. August 11, 2005. <http://www.kyrc.org/webnewspro/112381723236086.shtml>.) IDNR's definitions of "flowback water" and "produced water" are different. The two are distinguishably different enough that they are treated as separate types of fluid by both the Hydraulic Fracturing Regulatory Act and by the DNR Rules. Discharge of produced water onto the ground or into surface water or water drainage way is prohibited but it is not tested for radioactivity. This despite the fact that this fluid will be in contact with the naturally occurring radioactive elements in the ground for a longer period than the flowback and that it is much more likely to be radioactive. Problems: Failure to test produced water for radioactivity is problematic for a variety of reasons including: The health and safety of workers on the site who will be unaware of the levels of radioactivity they are being exposed to. The health and safety of workers transporting produced water who will also be in the dark regarding the levels of radioactivity they will be exposed to. The risk of storing radioactive material in tanks not created for storing radioactive materials. The risk of "recycling" produced water—radioactivity cannot be removed by recycling. The risk to the public in transporting radioactive materials Argonne National Laboratory recently cautioned about radiological doses: "It is commonly accepted that efforts should be undertaken at all times to keep radiological doses 'as low as reasonably achievable,' which is referred to as the ALARA principle or requirement." Overview of Radiological Dose and Risk Assessment (April 2011). DNR is failing to even adequately test for radioactivity and therefore, will not know the levels of radioactivity. How, then, can

## Fair Economy Illinois

---

DNR adequately protect workers and the general public? Elaboration: IDNR does not define a Fixed Date ( $\pm X$  days) for testing. Day 1, <Hour 1 test results will be orders of magnitude lower than either Day 2 or Day 10 tests results, and Day 10 tests results will be significantly lower than Day 80 ( $\pm 7$  days) results. Failure to specify a Fixed Test Date ( $\pm X$  days) renders test data so many irrelevant apples and oranges and allows companies to report suppressed, meaningless results by reporting Day 1, < 1 Hour data. The figure below, provided by the USGS, illustrates the nature of the problem. Please note that radium is not tested at Day 1, < 1 Hour. However, radium coprecipitates with barium, which is represented in total dissolved solids (TDS). It will therefore track TDS fairly closely. Conclusion: companies will be testing the very first flowback water to emerge from a fracked well. It will be Day 1, Minute 1 test results. 2.) There are two pits on a frack pad, one for "emergency" flowback and another, smaller one for drill cuttings and drilling mud. It is a basic principle in horizontal fracking to steer the drill bit through the horizontal strata with the highest gamma radiation readings (GAPI logs). The reason is that radioactivity correlates highly with total organic content (TOC) in the rock, and TOC correlates highly with oil and gas yields. This means that rock cuttings in the smaller drill mud and cuttings frack pit will often be more radioactive than flowback water. The IDNR knows this; yet it does not call for testing of drill bit pits as allowed under the Powers and duties section of the Act (§1- 15). 3.) The term "adjacent to" requires a "precise, clear standard" [IAPA, §100/5-20]. None is given. Does "adjacent to" mean 6 inches, 16 inches, 6 feet, 16 feet, or 60 feet? The IDNR does not say. 4.) Frack pad pipes and equipment can become incredibly radioactive over time. The very large temperature and pressure drops, as fluids move to the surface from thousands of feet underground, means that aqueous radioactive salts precipitate out as scale on pipes and equipment. The levels of radioactivity in pipe scale can exceed 100,000 picoCuries per gram and constitute a hazard to workers, or others who are exposed to recycled scrap metal from gas and oil operations. Yet, IDNR does not call on its General Assembly deferred "Power and authority" [Act, §1-15(e)] to test pipe, tanks, sludge, and equipment. This issue has been an issue in the oil and gas industry since the 1980s. Consequences: According to studies by the Illinois State Geological Survey, the Illinois New Albany Shale Formation, the source rock for our oil and gas reserves, has above average levels of uranium (29 ppm). Uranium decays into radium and thence radon. Both uranium and radium are water soluble. As noted, the U.S. Geological Survey has found oil field brine or produced water in Southern Illinois to have Radium226 levels that average more than 1,000 picoCuries / liter (USGS 1999). That reading is 67 times above the maximum contamination level of the EPA. Radium226 has a half life of 1,600 years. Uranium228 has a half life of 4.468 billion years. If these water soluble salts leach into our aquifers, nearby communities will require--if possible--very expensive water treatment for the next 1,000 years. We may have to return to rainwater harvesting with the modern equivalent of cisterns. The radioactive levels for produced water from shale gas operations are likely to be 2 to 4 times higher than oilfield brine -- on average, 2,000 to 4,000 picoCuries per liter. In addition, radon levels in methane, propane, and ethane can be dangerously high. When it becomes commercial to extract shale gas from the SE corner of the state, major markets, such as Springfield and Chicago, will only be 0.9 and 1.4 days removed from shale gas wellheads. Even though radon222 has a half life of only 3.8 days, the closeness of major Illinois retail gas markets will mean that large number of people will be breathing in high levels of radon when they cook meals. The average level of indoor exposure to radon in Illinois is already 4.4

## Fair Economy Illinois

---

pCi/L ( American Lung Association 2013). The EPA maximum level--the point at which corrective action should be taken--is 4.0 pCi/L, and the preferred level is =3.0 pCi/L. The turn to shale gas, with its high levels of radon, will also turn a major Illinois public health problem in the wrong direction. Radioactive scale in pipe and equipment presents another problem; high levels of radioactivity have been found in school playground equipment and bleachers in school sports stadiums in Mississippi and Texas. Do we want untested oil and gas field scrap metal sold into Illinois markets? Do we want our children exposed on a daily basis to radioactive metal? The present rules creates no barriers to such an outcome. The problems cited above are why Illinois, with its large number of nuclear power plants, has a Low-Level Radioactive Waste Management Act. It and OSHA are the applicable State and Federal agencies with respect to the issue of radioactive waste and work safety standards in settings with exposure to radioactivity. If we faithfully follow applicable State and federal laws, Illinois can minimize the pernicious problems other states are going to face from the uncontrolled release of radioactive elements into their water and soil and work and non-work settings. We should prevent these problem from the start. Cleanup, after the oil and gas industry is gone, will be dreadfully expensive.. Recommendations: 1. Define the test date as = Day 21, the point at which increases in test results begin to level off. 2. Test for "radioactivity" in (1) flowback/produced water, (2) drill cuttings, soil "adjacent to" (3) storage tanks and (4) reserve pits, and (5) pipes and well pad equipment. 3. Define "adjacent to" as between 6 and 12 inches with test samples to be taken within the top 6 inches of soil 4. The rules should also require that the requirements of the Illinois Low Level Radioactivity Waste Management Act be followed.

Sincerely, Molly Connor Chicago, IL 60605

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Act §1-75(a)7 requires radioactivity testing "once per well site" for (1) flowback water and ground "adjacent to" (2) storage tanks and (3) reserve pits. Act § 1-120 requires IDNR compliance with all "applicable federal, State, and local laws." One applicable State law is the Illinois Low-Level Radioactive Waste Management Act (PA 83-991 / 420ILCS20). Another is the Occupational Health and Safety Administration (OSHA) standards for workplace safety in settings with exposure to radioactivity (29 CFR 1910.1096). Rules §245.850(d)1-E and §245.850(e) are incomplete and deficient, and these inadequacies can "constitute a serious threat"--indeed, deadly threat-- "to the public interest, safety, or welfare" of Illinois citizens." Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Notably absent from these proposed rules is a requirement for the testing of "produced water", the fluid that returns from the well during the later stage of production (after flowback). Under the proposed rules, "produced water" can be stored on site and/or can be "recycled", yet there is no testing requirement. Naturally occurring radioactive material (NORM) is found in "produced water" also. See Technologically enhanced naturally occurring radioactive materials in the oil industry (TENORM), Nukleonika 2009; 54(1):3-9, and sources cited therein, especially for TENORM in produced water in the U.S., available at [http://www.nukleonika.pl/www/back/full/vol54\\_2009/v54n1p003f.pdf](http://www.nukleonika.pl/www/back/full/vol54_2009/v54n1p003f.pdf). See also NORM is also found on scale in oil pipes and on fracking equipment. (See Kentucky Resources Council Proposes Comprehensive Plan For Investigating Radiological Contamination In Martha Oil Field. August 11, 2005. <http://www.kyrc.org/webnewspro/112381723236086.shtml>.) IDNR's definitions of "flowback water" and "produced water" are different. DNR adequately protect workers and the general public? Elaboration: IDNR does not define a Fixed Date ( $\pm X$  days) for testing. Day 1, <Hour 1 test results will be orders of magnitude lower than either Day 2 or Day 10 tests results, and Day 10 tests results will be significantly lower than Day 80 ( $\pm 7$  days) results. Failure to specify a Fixed Test Date ( $\pm X$  days) renders test data so many irrelevant apples and oranges and allows companies to report suppressed, meaningless results by reporting Day 1, < 1 Hour data. The figure below, provided by the USGS, illustrates the nature of the problem. Please note that radium is not tested at Day 1, < 1 Hour. However, radium coprecipitates with barium, which is represented in total dissolved solids (TDS). It will therefore track TDS fairly closely. Conclusion: companies will be testing the very first flowback water to emerge from a fracked well. It will be Day 1, Minute 1 test results. 2.) There are two pits on a frack pad, one for "emergency" flowback and another, smaller one for drill cuttings and drilling mud. It is a basic principle in horizontal fracking to steer the drill bit through the horizontal strata with the highest gamma radiation readings (GAPI logs). The reason is that radioactivity correlates highly with total organic content (TOC) in the rock, and TOC correlates highly with oil and gas yields. This means that rock cuttings in the smaller drill mud and cuttings frack pit will often be more radioactive than flowback water. The IDNR knows this; yet it does not call for testing of drill bit pits as allowed under the Powers and duties section of the Act (§1- 15). 3.) The term "adjacent to" requires a "precise, clear standard" [IAPA, §100/5-20]. None is given. Does "adjacent to" mean 6 inches, 16 inches, 6 feet, 16 feet, or 60 feet? The IDNR does not say. 4.) Frack pad pipes and equipment can become incredibly radioactive over time. The very large temperature and pressure drops, as fluids move to the surface from thousands of feet underground, means that aqueous radioactive salts precipitate out as scale on pipes and equipment. The levels of radioactivity in pipe scale can exceed 100,000 picoCuries per gram and constitute a hazard to workers, or others who are exposed to recycled scrap metal from gas and oil operations. Yet, IDNR does not call on its General Assembly deferred "Power and authority" [Act, §1-15(e)] to test pipe, tanks, sludge, and equipment. This issue has been an issue in the oil and gas industry since the 1980s. Consequences: According to studies by the Illinois State Geological Survey, the Illinois New Albany Shale Formation, the source rock for our oil and gas reserves, has above average levels of uranium (29 ppm). Uranium decays into radium and thence radon. Both uranium and radium are water soluble. As noted, the U.S. Geological Survey has found oil field brine or produced water in Southern Illinois to have Radium226 levels that average more than 1,000 picoCuries / liter (USGS 1999). That reading is 67 times above the maximum contamination level of the EPA. Radium226 has a half life of 1,600 years. Uranium228 has a half life of 4.468 billion years. If these water soluble salts leach into our aquifers, nearby communities will require--if possible--very expensive water treatment for the next 1,000 years. We may have to return to rainwater harvesting with the modern equivalent of cisterns. The radioactive levels for produced water from shale gas operations are likely to be 2 to 4 times higher than oilfield brine -- on average, 2,000 to 4,000 picoCuries per liter. In addition, radon levels in methane, propane, and ethane can be dangerously high. When it becomes commercial to extract shale gas from the SE corner of the state, major markets, such as Springfield and Chicago, will only be 0.9 and 1.4 days removed from shale gas wellheads. Even though radon222 has a half life of only 3.8 days, the closeness of major Illinois retail gas markets will mean that large number of people will be breathing in high levels of radon when they cook meals. The average level of indoor exposure to radon in Illinois is already 4.4

## Fair Economy Illinois

---

pCi/L ( American Lung Association 2013). The EPA maximum level--the point at which corrective action should be taken--is 4.0 pCi/L, and the preferred level is =3.0 pCi/L. The turn to shale gas, with its high levels of radon, will also turn a major Illinois public health problem in the wrong direction. Radioactive scale in pipe and equipment presents another problem; high levels of radioactivity have been found in school playground equipment and bleachers in school sports stadiums in Mississippi and Texas. Do we want untested oil and gas field scrap metal sold into Illinois markets? Do we want our children exposed on a daily basis to radioactive metal? The present rules creates no barriers to such an outcome. The problems cited above are why Illinois, with its large number of nuclear power plants, has a Low-Level Radioactive Waste Management Act. It and OSHA are the applicable State and Federal agencies with respect to the issue of radioactive waste and work safety standards in settings with exposure to radioactivity. If we faithfully follow applicable State and federal laws, Illinois can minimize the pernicious problems other states are going to face from the uncontrolled release of radioactive elements into their water and soil and work and non-work settings. We should prevent these problem from the start. Cleanup, after the oil and gas industry is gone, will be dreadfully expensive.. Recommendations: 1. Define the test date as = Day 21, the point at which increases in test results begin to level off. 2. Test for "radioactivity" in (1) flowback/produced water, (2) drill cuttings, soil "adjacent to" (3) storage tanks and (4) reserve pits, and (5) pipes and well pad equipment. 3. Define "adjacent to" as between 6 and 12 inches with test samples to be taken within the top 6 inches of soil 4. The rules should also require that the requirements of the Illinois Low Level Radioactivity Waste Management Act be followed.

Sincerely, Nancy Penney Monticello, IL 61856

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Act §1-75(a)7 requires radioactivity testing "once per well site" for (1) flowback water and ground "adjacent to" (2) storage tanks and (3) reserve pits. Act § 1-120 requires IDNR compliance with all "applicable federal, State, and local laws." One applicable State law is the Illinois Low-Level Radioactive Waste Management Act (PA 83-991 / 420ILCS20). Another is the Occupational Health and Safety Administration (OSHA) standards for workplace safety in settings with exposure to radioactivity (29 CFR 1910.1096). Rules §245.850(d)1-E and §245.850(e) are incomplete and deficient, and these inadequacies can "constitute a serious threat"--indeed, deadly threat-- "to the public interest, safety, or welfare" of Illinois citizens." Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Notably absent from these proposed rules is a requirement for the testing of "produced water", the fluid that returns from the well during the later stage of production (after flowback). Under the proposed rules, "produced water" can be stored on site and/or can be "recycled", yet there is no testing requirement. Naturally occurring radioactive material (NORM) is found in "produced water" also. See Technologically enhanced naturally occurring radioactive materials in the oil industry (TENORM), Nukleonika 2009; 54(1):3-9, and sources cited therein, especially for TENORM in produced water in the U.S., available at [http://www.nukleonika.pl/www/back/full/vol54\\_2009/v54n1p003f.pdf](http://www.nukleonika.pl/www/back/full/vol54_2009/v54n1p003f.pdf). See also NORM is also found on scale in oil pipes and on fracking equipment. (See Kentucky Resources Council Proposes Comprehensive Plan For Investigating Radiological Contamination In Martha Oil Field. August 11, 2005. <http://www.kyrc.org/webnewspro/112381723236086.shtml>.) IDNR's definitions of "flowback water" and "produced water" are different. The two are distinguishably different enough that they are treated as separate types of fluid by both the Hydraulic Fracturing Regulatory Act and by the DNR Rules. Discharge of produced water onto the ground or into surface water or water drainage way is prohibited but it is not tested for radioactivity. This despite the fact that this fluid will be in contact with the naturally occurring radioactive elements in the ground for a longer period than the flowback and that it is much more likely to be radioactive. Problems: Failure to test produced water for radioactivity is problematic for a variety of reasons including: The health and safety of workers on the site who will be unaware of the levels of radioactivity they are being exposed to. The health and safety of workers transporting produced water who will also be in the dark regarding the levels of radioactivity they will be exposed to. The risk of storing radioactive material in tanks not created for storing radioactive materials. The risk of "recycling" produced water—radioactivity cannot be removed by recycling. The risk to the public in transporting radioactive materials Argonne National Laboratory recently cautioned about radiological doses: "It is commonly accepted that efforts should be undertaken at all times to keep radiological doses 'as low as reasonably achievable,' which is referred to as the ALARA principle or requirement." Overview of Radiological Dose and Risk Assessment (April 2011). DNR is failing to even adequately test for radioactivity and therefore, will not know the levels of radioactivity. How, then, can

## Fair Economy Illinois

---

DNR adequately protect workers and the general public? Elaboration: IDNR does not define a Fixed Date ( $\pm X$  days) for testing. Day 1, <Hour 1 test results will be orders of magnitude lower than either Day 2 or Day 10 tests results, and Day 10 tests results will be significantly lower than Day 80 ( $\pm 7$  days) results. Failure to specify a Fixed Test Date ( $\pm X$  days) renders test data so many irrelevant apples and oranges and allows companies to report suppressed, meaningless results by reporting Day 1, < 1 Hour data. The figure below, provided by the USGS, illustrates the nature of the problem. Please note that radium is not tested at Day 1, < 1 Hour. However, radium coprecipitates with barium, which is represented in total dissolved solids (TDS). It will therefore track TDS fairly closely. Conclusion: companies will be testing the very first flowback water to emerge from a fracked well. It will be Day 1, Minute 1 test results. 2.) DNR adequately protect workers and the general public? Elaboration: IDNR does not define a Fixed Date ( $\pm X$  days) for testing. Day 1, <Hour 1 test results will be orders of magnitude lower than either Day 2 or Day 10 tests results, and Day 10 tests results will be significantly lower than Day 80 ( $\pm 7$  days) results. Failure to specify a Fixed Test Date ( $\pm X$  days) renders test data so many irrelevant apples and oranges and allows companies to report suppressed, meaningless results by reporting Day 1, < 1 Hour data. The figure below, provided by the USGS, illustrates the nature of the problem. Please note that radium is not tested at Day 1, < 1 Hour. However, radium coprecipitates with barium, which is represented in total dissolved solids (TDS). It will therefore track TDS fairly closely. Conclusion: companies will be testing the very first flowback water to emerge from a fracked well. It will be Day 1, Minute 1 test results. 2.) There are two pits on a frack pad, one for "emergency" flowback and another, smaller one for drill cuttings and drilling mud. It is a basic principle in horizontal fracking to steer the drill bit through the horizontal strata with the highest gamma radiation readings (GAPI logs). The reason is that radioactivity correlates highly with total organic content (TOC) in the rock, and TOC correlates highly with oil and gas yields. This means that rock cuttings in the smaller drill mud and cuttings frack pit will often be more radioactive than flowback water. The IDNR knows this; yet it does not call for testing of drill bit pits as allowed under the Powers and duties section of the Act (§1- 15). 3.) The term "adjacent to" requires a "precise, clear standard" [IAPA, §100/5-20]. None is given. Does "adjacent to" mean 6 inches, 16 inches, 6 feet, 16 feet, or 60 feet? The IDNR does not say. 4.) Frack pad pipes and equipment can become incredibly radioactive over time. The very large temperature and pressure drops, as fluids move to the surface from thousands of feet underground, means that aqueous radioactive salts precipitate out as scale on pipes and equipment. The levels of radioactivity in pipe scale can exceed 100,000 picoCuries per gram and constitute a hazard to workers, or others who are exposed to recycled scrap metal from gas and oil operations. Yet, IDNR does not call on its General Assembly deferred "Power and authority" [Act, §1-15(e)] to test pipe, tanks, sludge, and equipment. This issue has been an issue in the oil and gas industry since the 1980s. Consequences: According to studies by the Illinois State Geological Survey, the Illinois New Albany Shale Formation, the source rock for our oil and gas reserves, has above average levels of uranium (29 ppm). Uranium decays into radium and thence radon. Both uranium and radium are water soluble. As noted, the U.S. Geological Survey has found oil field brine or produced water in Southern Illinois to have Radium226 levels that average more than 1,000 picoCuries / liter (USGS 1999). That reading is 67 times above the maximum contamination level of the EPA. Radium226 has a half life of 1,600 years. Uranium228 has a half life of 4.468 billion years. If these water soluble salts leach into our aquifers, nearby communities will require--if possible--very expensive water treatment for the next 1,000 years. We may have to return to rainwater harvesting with the modern equivalent of cisterns. The radioactive levels for produced water from shale gas operations are likely to be 2 to 4 times higher than oilfield brine -- on average, 2,000 to 4,000 picoCuries per liter. In addition, radon levels in methane, propane, and ethane can be dangerously high. When it becomes commercial to extract shale gas from the SE corner of the state, major markets, such as Springfield and Chicago, will only be 0.9 and 1.4 days removed from shale gas wellheads. Even though radon222 has a half life of only 3.8 days, the closeness of major Illinois retail gas markets will mean that large number of people will be breathing in high levels of radon when they cook meals. The average level of indoor exposure to radon in Illinois is already 4.4

## Fair Economy Illinois

---

pCi/L ( American Lung Association 2013). The EPA maximum level--the point at which corrective action should be taken--is 4.0 pCi/L, and the preferred level is =3.0 pCi/L. The turn to shale gas, with its high levels of radon, will also turn a major Illinois public health problem in the wrong direction. Radioactive scale in pipe and equipment presents another problem; high levels of radioactivity have been found in school playground equipment and bleachers in school sports stadiums in Mississippi and Texas. Do we want untested oil and gas field scrap metal sold into Illinois markets? Do we want our children exposed on a daily basis to radioactive metal? The present rules creates no barriers to such an outcome. The problems cited above are why Illinois, with its large number of nuclear power plants, has a Low-Level Radioactive Waste Management Act. It and OSHA are the applicable State and Federal agencies with respect to the issue of radioactive waste and work safety standards in settings with exposure to radioactivity. If we faithfully follow applicable State and federal laws, Illinois can minimize the pernicious problems other states are going to face from the uncontrolled release of radioactive elements into their water and soil and work and non-work settings. We should prevent these problem from the start. Cleanup, after the oil and gas industry is gone, will be dreadfully expensive.. Recommendations: 1. Define the test date as = Day 21, the point at which increases in test results begin to level off. 2. Test for "radioactivity" in (1) flowback/produced water, (2) drill cuttings, soil "adjacent to" (3) storage tanks and (4) reserve pits, and (5) pipes and well pad equipment. 3. Define "adjacent to" as between 6 and 12 inches with test samples to be taken within the top 6 inches of soil 4. The rules should also require that the requirements of the Illinois Low Level Radioactivity Waste Management Act be followed.

Sincerely, Noah Hellermann New York, IL 11218

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Act §1-75(a)7 requires radioactivity testing "once per well site" for (1) flowback water and ground "adjacent to" (2) storage tanks and (3) reserve pits. Act § 1-120 requires IDNR compliance with all "applicable federal, State, and local laws." One applicable State law is the Illinois Low-Level Radioactive Waste Management Act (PA 83-991 / 420ILCS20). Another is the Occupational Health and Safety Administration (OSHA) standards for workplace safety in settings with exposure to radioactivity (29 CFR 1910.1096). Rules §245.850(d)1-E and §245.850(e) are incomplete and deficient, and these inadequacies can "constitute a serious threat"--indeed, deadly threat-- "to the public interest, safety, or welfare" of Illinois citizens." Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Notably absent from these proposed rules is a requirement for the testing of "produced water", the fluid that returns from the well during the later stage of production (after flowback). Under the proposed rules, "produced water" can be stored on site and/or can be "recycled", yet there is no testing requirement. Naturally occurring radioactive material (NORM) is found in "produced water" also. See Technologically enhanced naturally occurring radioactive materials in the oil industry (TENORM), Nukleonika 2009; 54(1):3-9, and sources cited therein, especially for TENORM in produced water in the U.S., available at [http://www.nukleonika.pl/www/back/full/vol54\\_2009/v54n1p003f.pdf](http://www.nukleonika.pl/www/back/full/vol54_2009/v54n1p003f.pdf). See also NORM is also found on scale in oil pipes and on fracking equipment. (See Kentucky Resources Council Proposes Comprehensive Plan For Investigating Radiological Contamination In Martha Oil Field. August 11, 2005. <http://www.kyrc.org/webnewspro/112381723236086.shtml>.) IDNR's definitions of "flowback water" and "produced water" are different. The two are distinguishably different enough that they are treated as separate types of fluid by both the Hydraulic Fracturing Regulatory Act and by the DNR Rules. Discharge of produced water onto the ground or into surface water or water drainage way is prohibited but it is not tested for radioactivity. This despite the fact that this fluid will be in contact with the naturally occurring radioactive elements in the ground for a longer period than the flowback and that it is much more likely to be radioactive. Problems: Failure to test produced water for radioactivity is problematic for a variety of reasons including: The health and safety of workers on the site who will be unaware of the levels of radioactivity they are being exposed to. The health and safety of workers transporting produced water who will also be in the dark regarding the levels of radioactivity they will be exposed to. The risk of storing radioactive material in tanks not created for storing radioactive materials. The risk of "recycling" produced water—radioactivity cannot be removed by recycling. The risk to the public in transporting radioactive materials Argonne National Laboratory recently cautioned about radiological doses: "It is commonly accepted that efforts should be undertaken at all times to keep radiological doses 'as low as reasonably achievable,' which is referred to as the ALARA principle or requirement." Overview of Radiological Dose and Risk Assessment (April 2011). DNR is failing to even adequately test for radioactivity and therefore, will not know the levels of radioactivity. How, then, can

## Fair Economy Illinois

---

DNR adequately protect workers and the general public? Elaboration: IDNR does not define a Fixed Date ( $\pm X$  days) for testing. Day 1, <Hour 1 test results will be orders of magnitude lower than either Day 2 or Day 10 tests results, and Day 10 tests results will be significantly lower than Day 80 ( $\pm 7$  days) results. Failure to specify a Fixed Test Date ( $\pm X$  days) renders test data so many irrelevant apples and oranges and allows companies to report suppressed, meaningless results by reporting Day 1, < 1 Hour data. The figure below, provided by the USGS, illustrates the nature of the problem. Please note that radium is not tested at Day 1, < 1 Hour. However, radium coprecipitates with barium, which is represented in total dissolved solids (TDS). It will therefore track TDS fairly closely. Conclusion: companies will be testing the very first flowback water to emerge from a fracked well. It will be Day 1, Minute 1 test results. 2.) There are two pits on a frack pad, one for "emergency" flowback and another, smaller one for drill cuttings and drilling mud. It is a basic principle in horizontal fracking to steer the drill bit through the horizontal strata with the highest gamma radiation readings (GAPI logs). The reason is that radioactivity correlates highly with total organic content (TOC) in the rock, and TOC correlates highly with oil and gas yields. This means that rock cuttings in the smaller drill mud and cuttings frack pit will often be more radioactive than flowback water. The IDNR knows this; yet it does not call for testing of drill bit pits as allowed under the Powers and duties section of the Act (§1- 15). 3.) The term "adjacent to" requires a "precise, clear standard" [IAPA, §100/5-20]. None is given. Does "adjacent to" mean 6 inches, 16 inches, 6 feet, 16 feet, or 60 feet? The IDNR does not say. 4.) Frack pad pipes and equipment can become incredibly radioactive over time. The very large temperature and pressure drops, as fluids move to the surface from thousands of feet underground, means that aqueous radioactive salts precipitate out as scale on pipes and equipment. The levels of radioactivity in pipe scale can exceed 100,000 picoCuries per gram and constitute a hazard to workers, or others who are exposed to recycled scrap metal from gas and oil operations. Yet, IDNR does not call on its General Assembly deferred "Power and authority" [Act, §1-15(e)] to test pipe, tanks, sludge, and equipment. This issue has been an issue in the oil and gas industry since the 1980s. Consequences: According to studies by the Illinois State Geological Survey, the Illinois New Albany Shale Formation, the source rock for our oil and gas reserves, has above average levels of uranium (29 ppm). Uranium decays into radium and thence radon. Both uranium and radium are water soluble. As noted, the U.S. Geological Survey has found oil field brine or produced water in Southern Illinois to have Radium226 levels that average more than 1,000 picoCuries / liter (USGS 1999). That reading is 67 times above the maximum contamination level of the EPA. Radium226 has a half life of 1,600 years. Uranium228 has a half life of 4.468 billion years. If these water soluble salts leach into our aquifers, nearby communities will require--if possible--very expensive water treatment for the next 1,000 years. We may have to return to rainwater harvesting with the modern equivalent of cisterns. The radioactive levels for produced water from shale gas operations are likely to be 2 to 4 times higher than oilfield brine -- on average, 2,000 to 4,000 picoCuries per liter. In addition, radon levels in methane, propane, and ethane can be dangerously high. When it becomes commercial to extract shale gas from the SE corner of the state, major markets, such as Springfield and Chicago, will only be 0.9 and 1.4 days removed from shale gas wellheads. In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Act §1-75(a)7 requires radioactivity testing "once per well site" for (1) flowback water and ground "adjacent to" (2) storage tanks and (3) reserve pits. Act § 1-120 requires IDNR compliance with all "applicable federal, State, and local laws." One applicable State law is the Illinois Low-Level Radioactive Waste Management Act (PA 83-991 / 420ILCS20). Another is the Occupational Health and Safety Administration (OSHA) standards for workplace safety in settings with exposure to radioactivity (29 CFR 1910.1096). Rules §245.850(d)1-E and §245.850(e) are incomplete and deficient, and these inadequacies can "constitute a serious threat"--indeed, deadly threat-- "to the public interest, safety, or welfare" of Illinois citizens." Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Notably absent from these proposed rules is a requirement for the testing of "produced water", the fluid that returns from the well during the later stage of production (after flowback). Under the proposed rules, "produced water" can be stored on site and/or can be "recycled", yet there is no testing requirement. Naturally occurring radioactive material (NORM) is found in "produced water" also. See Technologically enhanced naturally occurring radioactive materials in the oil industry (TENORM), Nukleonika 2009; 54(1):3-9, and sources cited therein, especially for TENORM in produced water in the U.S., available at [http://www.nukleonika.pl/www/back/full/vol54\\_2009/v54n1p003f.pdf](http://www.nukleonika.pl/www/back/full/vol54_2009/v54n1p003f.pdf). See also NORM is also found on scale in oil pipes and on fracking equipment. (See Kentucky Resources Council Proposes Comprehensive Plan For Investigating Radiological Contamination In Martha Oil Field. August 11, 2005. <http://www.kyrc.org/webnewspro/112381723236086.shtml>.) IDNR's definitions of "flowback water" and "produced water" are different. The two are distinguishably different enough that they are treated as separate types of fluid by both the Hydraulic Fracturing Regulatory Act and by the DNR Rules. Discharge of produced water onto the ground or into surface water or water drainage way is prohibited but it is not tested for radioactivity. This despite the fact that this fluid will be in contact with the naturally occurring radioactive elements in the ground for a longer period than the flowback and that it is much more likely to be radioactive. Problems: Failure to test produced water for radioactivity is problematic for a variety of reasons including: The health and safety of workers on the site who will be unaware of the levels of radioactivity they are being exposed to. The health and safety of workers transporting produced water who will also be in the dark regarding the levels of radioactivity they will be exposed to. The risk of storing radioactive material in tanks not created for storing radioactive materials. The risk of "recycling" produced water—radioactivity cannot be removed by recycling. The risk to the public in transporting radioactive materials Argonne National Laboratory recently cautioned about radiological doses: "It is commonly accepted that efforts should be undertaken at all times to keep radiological doses 'as low as reasonably achievable,' which is referred to as the ALARA principle or requirement." Overview of Radiological Dose and Risk Assessment (April 2011). DNR is failing to even adequately test for radioactivity and therefore, will not know the levels of radioactivity. How, then, can

## Fair Economy Illinois

---

DNR adequately protect workers and the general public? Elaboration: IDNR does not define a Fixed Date ( $\pm X$  days) for testing. Day 1, <Hour 1 test results will be orders of magnitude lower than either Day 2 or Day 10 tests results, and Day 10 tests results will be significantly lower than Day 80 ( $\pm 7$  days) results. Failure to specify a Fixed Test Date ( $\pm X$  days) renders test data so many irrelevant apples and oranges and allows companies to report suppressed, meaningless results by reporting Day 1, < 1 Hour data. The figure below, provided by the USGS, illustrates the nature of the problem. Please note that radium is not tested at Day 1, < 1 Hour. However, radium coprecipitates with barium, which is represented in total dissolved solids (TDS). It will therefore track TDS fairly closely. Conclusion: companies will be testing the very first flowback water to emerge from a fracked well. It will be Day 1, Minute 1 test results. 2.) There are two pits on a frack pad, one for "emergency" flowback and another, smaller one for drill cuttings and drilling mud. It is a basic principle in horizontal fracking to steer the drill bit through the horizontal strata with the highest gamma radiation readings (GAPI logs). The reason is that radioactivity correlates highly with total organic content (TOC) in the rock, and TOC correlates highly with oil and gas yields. This means that rock cuttings in the smaller drill mud and cuttings frack pit will often be more radioactive than flowback water. The IDNR knows this; yet it does not call for testing of drill bit pits as allowed under the Powers and duties section of the Act (§1- 15). 3.) The term "adjacent to" requires a "precise, clear standard" [IAPA, §100/5-20]. None is given. Does "adjacent to" mean 6 inches, 16 inches, 6 feet, 16 feet, or 60 feet? The IDNR does not say. 4.) Frack pad pipes and equipment can become incredibly radioactive over time. The very large temperature and pressure drops, as fluids move to the surface from thousands of feet underground, means that aqueous radioactive salts precipitate out as scale on pipes and equipment. The levels of radioactivity in pipe scale can exceed 100,000 picoCuries per gram and constitute a hazard to workers, or others who are exposed to recycled scrap metal from gas and oil operations. Yet, IDNR does not call on its General Assembly deferred "Power and authority" [Act, §1-15(e)] to test pipe, tanks, sludge, and equipment. This issue has been an issue in the oil and gas industry since the 1980s. Consequences: According to studies by the Illinois State Geological Survey, the Illinois New Albany Shale Formation, the source rock for our oil and gas reserves, has above average levels of uranium (29 ppm). Uranium decays into radium and thence radon. Both uranium and radium are water soluble. As noted, the U.S. Geological Survey has found oil field brine or produced water in Southern Illinois to have Radium226 levels that average more than 1,000 picoCuries / liter (USGS 1999). That reading is 67 times above the maximum contamination level of the EPA. Radium226 has a half life of 1,600 years. Uranium228 has a half life of 4.468 billion years. If these water soluble salts leach into our aquifers, nearby communities will require--if possible--very expensive water treatment for the next 1,000 years. We may have to return to rainwater harvesting with the modern equivalent of cisterns. The radioactive levels for produced water from shale gas operations are likely to be 2 to 4 times higher than oilfield brine -- on average, 2,000 to 4,000 picoCuries per liter. In addition, radon levels in methane, propane, and ethane can be dangerously high. When it becomes commercial to extract shale gas from the SE corner of the state, major markets, such as Springfield and Chicago, will only be 0.9 and 1.4 days removed from shale gas wellheads. Even though radon222 has a half life of only 3.8 days, the closeness of major Illinois retail gas markets will mean that large number of people will be breathing in high levels of radon when they cook meals. The average level of indoor exposure to radon in Illinois is already 4.4

## Fair Economy Illinois

---

pCi/L ( American Lung Association 2013). The EPA maximum level--the point at which corrective action should be taken--is 4.0 pCi/L, and the preferred level is =3.0 pCi/L. The turn to shale gas, with its high levels of radon, will also turn a major Illinois public health problem in the wrong direction. Radioactive scale in pipe and equipment presents another problem; high levels of radioactivity have been found in school playground equipment and bleachers in school sports stadiums in Mississippi and Texas. Do we want untested oil and gas field scrap metal sold into Illinois markets? Do we want our children exposed on a daily basis to radioactive metal? The present rules creates no barriers to such an outcome. The problems cited above are why Illinois, with its large number of nuclear power plants, has a Low-Level Radioactive Waste Management Act. It and OSHA are the applicable State and Federal agencies with respect to the issue of radioactive waste and work safety standards in settings with exposure to radioactivity. If we faithfully follow applicable State and federal laws, Illinois can minimize the pernicious problems other states are going to face from the uncontrolled release of radioactive elements into their water and soil and work and non-work settings. We should prevent these problem from the start. Cleanup, after the oil and gas industry is gone, will be dreadfully expensive.. Recommendations: 1. Define the test date as = Day 21, the point at which increases in test results begin to level off. 2. Test for "radioactivity" in (1) flowback/produced water, (2) drill cuttings, soil "adjacent to" (3) storage tanks and (4) reserve pits, and (5) pipes and well pad equipment. 3. Define "adjacent to" as between 6 and 12 inches with test samples to be taken within the top 6 inches of soil 4. The rules should also require that the requirements of the Illinois Low Level Radioactivity Waste Management Act be followed.

Sincerely, Olivia Stovicek Chicago, IL 60637

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Act §1-75(a)7 requires radioactivity testing "once per well site" for (1) flowback water and ground "adjacent to" (2) storage tanks and (3) reserve pits. Act § 1-120 requires IDNR compliance with all "applicable federal, State, and local laws." One applicable State law is the Illinois Low-Level Radioactive Waste Management Act (PA 83-991 / 420ILCS20). Another is the Occupational Health and Safety Administration (OSHA) standards for workplace safety in settings with exposure to radioactivity (29 CFR 1910.1096). Rules §245.850(d)1-E and §245.850(e) are incomplete and deficient, and these inadequacies can "constitute a serious threat"--indeed, deadly threat-- "to the public interest, safety, or welfare" of Illinois citizens." Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Notably absent from these proposed rules is a requirement for the testing of "produced water", the fluid that returns from the well during the later stage of production (after flowback). Under the proposed rules, "produced water" can be stored on site and/or can be "recycled", yet there is no testing requirement. Naturally occurring radioactive material (NORM) is found in "produced water" also. See Technologically enhanced naturally occurring radioactive materials in the oil industry (TENORM), Nukleonika 2009; 54(1):3-9, and sources cited therein, especially for TENORM in produced water in the U.S., available at [http://www.nukleonika.pl/www/back/full/vol54\\_2009/v54n1p003f.pdf](http://www.nukleonika.pl/www/back/full/vol54_2009/v54n1p003f.pdf). See also NORM is also found on scale in oil pipes and on fracking equipment. (See Kentucky Resources Council Proposes Comprehensive Plan For Investigating Radiological Contamination In Martha Oil Field. August 11, 2005. <http://www.kyrc.org/webnewspro/112381723236086.shtml>.) IDNR's definitions of "flowback water" and "produced water" are different. The two are distinguishably different enough that they are treated as separate types of fluid by both the Hydraulic Fracturing Regulatory Act and by the DNR Rules. Discharge of produced water onto the ground or into surface water or water drainage way is prohibited but it is not tested for radioactivity. This despite the fact that this fluid will be in contact with the naturally occurring radioactive elements in the ground for a longer period than the flowback and that it is much more likely to be radioactive. Problems: Failure to test produced water for radioactivity is problematic for a variety of reasons including: The health and safety of workers on the site who will be unaware of the levels of radioactivity they are being exposed to. The health and safety of workers transporting produced water who will also be in the dark regarding the levels of radioactivity they will be exposed to. The risk of storing radioactive material in tanks not created for storing radioactive materials. The risk of "recycling" produced water—radioactivity cannot be removed by recycling. The risk to the public in transporting radioactive materials Argonne National Laboratory recently cautioned about radiological doses: "It is commonly accepted that efforts should be undertaken at all times to keep radiological doses 'as low as reasonably achievable,' which is referred to as the ALARA principle or requirement." Overview of Radiological Dose and Risk Assessment (April 2011). DNR is failing to even adequately test for radioactivity and therefore, will not know the levels of radioactivity. How, then, can

DNR adequately protect workers and the general public? Elaboration: IDNR does not define a Fixed Date ( $\pm X$  days) for testing. Day 1, <Hour 1 test results will be orders of magnitude lower than either Day 2 or Day 10 tests results, and Day 10 tests results will be significantly lower than Day 80 ( $\pm 7$  days) results. Failure to specify a Fixed Test Date ( $\pm X$  days) renders test data so many irrelevant apples and oranges and allows companies to report suppressed, meaningless results by reporting Day 1, < 1 Hour data. The figure below, provided by the USGS, illustrates the nature of the problem. Please note that radium is not tested at Day 1, < 1 Hour. However, radium coprecipitates with barium, which is represented in total dissolved solids (TDS). It will therefore track TDS fairly closely. Conclusion: companies will be testing the very first flowback water to emerge from a fracked well. It will be Day 1, Minute 1 test results. 2.) There are two pits on a frack pad, one for "emergency" flowback and another, smaller one for drill cuttings and drilling mud. It is a basic principle in horizontal fracking to steer the drill bit through the horizontal strata with the highest gamma radiation readings (GAPI logs). The reason is that radioactivity correlates highly with total organic content (TOC) in the rock, and TOC correlates highly with oil and gas yields. This means that rock cuttings in the smaller drill mud and cuttings frack pit will often be more radioactive than flowback water. The IDNR knows this; yet it does not call for testing of drill bit pits as allowed under the Powers and duties section of the Act (§1- 15). 3.) The term "adjacent to" requires a "precise, clear standard" [IAPA, §100/5-20]. None is given. Does "adjacent to" mean 6 inches, 16 inches, 6 feet, 16 feet, or 60 feet? The IDNR does not say. 4.) Frack pad pipes and equipment can become incredibly radioactive over time. The very large temperature and pressure drops, as fluids move to the surface from thousands of feet underground, means that aqueous radioactive salts precipitate out as scale on pipes and equipment. The levels of radioactivity in pipe scale can exceed 100,000 picoCuries per gram and constitute a hazard to workers, or others who are exposed to recycled scrap metal from gas and oil operations. Yet, IDNR does not call on its General Assembly deferred "Power and authority" [Act, §1-15(e)] to test pipe, tanks, sludge, and equipment. This issue has been an issue in the oil and gas industry since the 1980s. Consequences: According to studies by the Illinois State Geological Survey, the Illinois New Albany Shale Formation, the source rock for our oil and gas reserves, has above average levels of uranium (29 ppm). Uranium decays into radium and thence radon. Both uranium and radium are water soluble. As noted, the U.S. Geological Survey has found oil field brine or produced water in Southern Illinois to have Radium226 levels that average more than 1,000 picoCuries / liter (USGS 1999). That reading is 67 times above the maximum contamination level of the EPA. Radium226 has a half life of 1,600 years. Uranium228 has a half life of 4.468 billion years. If these water soluble salts leach into our aquifers, nearby communities will require--if possible--very expensive water treatment for the next 1,000 years. We may have to return to rainwater harvesting with the modern equivalent of cisterns. The radioactive levels for produced water from shale gas operations are likely to be 2 to 4 times higher than oilfield brine -- on average, 2,000 to 4,000 picoCuries per liter. In addition, radon levels in methane, propane, and ethane can be dangerously high. When it becomes commercial to extract shale gas from the SE corner of the state, major markets, such as Springfield and Chicago, will only be 0.9 and 1.4 days removed from shale gas wellheads. Even though radon222 has a half life of only 3.8 days, the closeness of major Illinois retail gas markets will mean that large number of people will be breathing in high levels of radon when they cook meals. The average level of indoor exposure to radon in Illinois is already 4.4

## Fair Economy Illinois

---

pCi/L ( American Lung Association 2013). The EPA maximum level--the point at which corrective action should be taken--is 4.0 pCi/L, and the preferred level is =3.0 pCi/L. The turn to shale gas, with its high levels of radon, will also turn a major Illinois public health problem in the wrong direction. Radioactive scale in pipe and equipment presents another problem; high levels of radioactivity have been found in school playground equipment and bleachers in school sports stadiums in Mississippi and Texas. Do we want untested oil and gas field scrap metal sold into Illinois markets? Do we want our children exposed on a daily basis to radioactive metal? The present rules creates no barriers to such an outcome. The problems cited above are why Illinois, with its large number of nuclear power plants, has a Low-Level Radioactive Waste Management Act. It and OSHA are the applicable State and Federal agencies with respect to the issue of radioactive waste and work safety standards in settings with exposure to radioactivity. If we faithfully follow applicable State and federal laws, Illinois can minimize the pernicious problems other states are going to face from the uncontrolled release of radioactive elements into their water and soil and work and non-work settings. We should prevent these problem from the start. Cleanup, after the oil and gas industry is gone, will be dreadfully expensive.. Recommendations: 1. Define the test date as = Day 21, the point at which increases in test results begin to level off. 2. Test for "radioactivity" in (1) flowback/produced water, (2) drill cuttings, soil "adjacent to" (3) storage tanks and (4) reserve pits, and (5) pipes and well pad equipment. 3. Define "adjacent to" as between 6 and 12 inches with test samples to be taken within the top 6 inches of soil 4. The rules should also require that the requirements of the Illinois Low Level Radioactivity Waste Management Act be followed.

Sincerely, Patricia Simpson Philo, IL 61864

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Act §1-75(a)7 requires radioactivity testing "once per well site" for (1) flowback water and ground "adjacent to" (2) storage tanks and (3) reserve pits. Act § 1-120 requires IDNR compliance with all "applicable federal, State, and local laws." One applicable State law is the Illinois Low-Level Radioactive Waste Management Act (PA 83-991 / 420ILCS20). Another is the Occupational Health and Safety Administration (OSHA) standards for workplace safety in settings with exposure to radioactivity (29 CFR 1910.1096). Rules §245.850(d)1-E and §245.850(e) are incomplete and deficient, and these inadequacies can "constitute a serious threat"--indeed, deadly threat-- "to the public interest, safety, or welfare" of Illinois citizens." Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Notably absent from these proposed rules is a requirement for the testing of "produced water", the fluid that returns from the well during the later stage of production (after flowback). Under the proposed rules, "produced water" can be stored on site and/or can be "recycled", yet there is no testing requirement. Naturally occurring radioactive material (NORM) is found in "produced water" also. See Technologically enhanced naturally occurring radioactive materials in the oil industry (TENORM), Nukleonika 2009; 54(1):3-9, and sources cited therein, especially for TENORM in produced water in the U.S., available at [http://www.nukleonika.pl/www/back/full/vol54\\_2009/v54n1p003f.pdf](http://www.nukleonika.pl/www/back/full/vol54_2009/v54n1p003f.pdf). See also NORM is also found on scale in oil pipes and on fracking equipment. (See Kentucky Resources Council Proposes Comprehensive Plan For Investigating Radiological Contamination In Martha Oil Field. August 11, 2005. <http://www.kyrc.org/webnewspro/112381723236086.shtml>.) IDNR's definitions of "flowback water" and "produced water" are different. The two are distinguishably different enough that they are treated as separate types of fluid by both the Hydraulic Fracturing Regulatory Act and by the DNR Rules. Discharge of produced water onto the ground or into surface water or water drainage way is prohibited but it is not tested for radioactivity. This despite the fact that this fluid will be in contact with the naturally occurring radioactive elements in the ground for a longer period than the flowback and that it is much more likely to be radioactive. Problems: Failure to test produced water for radioactivity is problematic for a variety of reasons including: The health and safety of workers on the site who will be unaware of the levels of radioactivity they are being exposed to. The health and safety of workers transporting produced water who will also be in the dark regarding the levels of radioactivity they will be exposed to. The risk of storing radioactive material in tanks not created for storing radioactive materials. The risk of "recycling" produced water—radioactivity cannot be removed by recycling. The risk to the public in transporting radioactive materials Argonne National Laboratory recently cautioned about radiological doses: "It is commonly accepted that efforts should be undertaken at all times to keep radiological doses 'as low as reasonably achievable,' which is referred to as the ALARA principle or requirement." The risk of storing radioactive material in tanks not created for storing radioactive materials. The risk of "recycling" produced water—radioactivity cannot be removed by recycling. The risk to the public in transporting radioactive materials Argonne National Laboratory recently cautioned about radiological doses: "It is commonly accepted that efforts should be undertaken at all times to keep radiological doses 'as low as reasonably achievable,' which is referred to as the ALARA principle or requirement." Overview of Radiological Dose and Risk Assessment (April 2011). DNR is failing to even adequately test for radioactivity and therefore, will not know the levels of radioactivity. How, then, can

## Fair Economy Illinois

---

DNR adequately protect workers and the general public? Elaboration: IDNR does not define a Fixed Date ( $\pm X$  days) for testing. Day 1, <Hour 1 test results will be orders of magnitude lower than either Day 2 or Day 10 tests results, and Day 10 tests results will be significantly lower than Day 80 ( $\pm 7$  days) results. Failure to specify a Fixed Test Date ( $\pm X$  days) renders test data so many irrelevant apples and oranges and allows companies to report suppressed, meaningless results by reporting Day 1, < 1 Hour data. The figure below, provided by the USGS, illustrates the nature of the problem. Please note that radium is not tested at Day 1, < 1 Hour. However, radium coprecipitates with barium, which is represented in total dissolved solids (TDS). It will therefore track TDS fairly closely. Conclusion: companies will be testing the very first flowback water to emerge from a fracked well. It will be Day 1, Minute 1 test results. 2.) There are two pits on a frack pad, one for "emergency" flowback and another, smaller one for drill cuttings and drilling mud. It is a basic principle in horizontal fracking to steer the drill bit through the horizontal strata with the highest gamma radiation readings (GAPI logs). The reason is that radioactivity correlates highly with total organic content (TOC) in the rock, and TOC correlates highly with oil and gas yields. This means that rock cuttings in the smaller drill mud and cuttings frack pit will often be more radioactive than flowback water. The IDNR knows this; yet it does not call for testing of drill bit pits as allowed under the Powers and duties section of the Act (§1- 15). 3.) The term "adjacent to" requires a "precise, clear standard" [IAPA, §100/5-20]. None is given. Does "adjacent to" mean 6 inches, 16 inches, 6 feet, 16 feet, or 60 feet? The IDNR does not say. 4.) Frack pad pipes and equipment can become incredibly radioactive over time. The very large temperature and pressure drops, as fluids move to the surface from thousands of feet underground, means that aqueous radioactive salts precipitate out as scale on pipes and equipment. The levels of radioactivity in pipe scale can exceed 100,000 picoCuries per gram and constitute a hazard to workers, or others who are exposed to recycled scrap metal from gas and oil operations. Yet, IDNR does not call on its General Assembly deferred "Power and authority" [Act, §1-15(e)] to test pipe, tanks, sludge, and equipment. This issue has been an issue in the oil and gas industry since the 1980s. Consequences: According to studies by the Illinois State Geological Survey, the Illinois New Albany Shale Formation, the source rock for our oil and gas reserves, has above average levels of uranium (29 ppm). Uranium decays into radium and thence radon. Both uranium and radium are water soluble. As noted, the U.S. Geological Survey has found oil field brine or produced water in Southern Illinois to have Radium226 levels that average more than 1,000 picoCuries / liter (USGS 1999). That reading is 67 times above the maximum contamination level of the EPA. Radium226 has a half life of 1,600 years. Uranium228 has a half life of 4.468 billion years. If these water soluble salts leach into our aquifers, nearby communities will require--if possible--very expensive water treatment for the next 1,000 years. We may have to return to rainwater harvesting with the modern equivalent of cisterns. The radioactive levels for produced water from shale gas operations are likely to be 2 to 4 times higher than oilfield brine -- on average, 2,000 to 4,000 picoCuries per liter. In addition, radon levels in methane, propane, and ethane can be dangerously high. When it becomes commercial to extract shale gas from the SE corner of the state, major markets, such as Springfield and Chicago, will only be 0.9 and 1.4 days removed from shale gas wellheads. Even though radon222 has a half life of only 3.8 days, the closeness of major Illinois retail gas markets will mean that large number of people will be breathing in high levels of radon when they cook meals. The average level of indoor exposure to radon in Illinois is already 4.4

## Fair Economy Illinois

---

pCi/L ( American Lung Association 2013). The EPA maximum level--the point at which corrective action should be taken--is 4.0 pCi/L, and the preferred level is =3.0 pCi/L. The turn to shale gas, with its high levels of radon, will also turn a major Illinois public health problem in the wrong direction. Radioactive scale in pipe and equipment presents another problem; high levels of radioactivity have been found in school playground equipment and bleachers in school sports stadiums in Mississippi and Texas. Do we want untested oil and gas field scrap metal sold into Illinois markets? Do we want our children exposed on a daily basis to radioactive metal? The present rules creates no barriers to such an outcome. The problems cited above are why Illinois, with its large number of nuclear power plants, has a Low-Level Radioactive Waste Management Act. It and OSHA are the applicable State and Federal agencies with respect to the issue of radioactive waste and work safety standards in settings with exposure to radioactivity. If we faithfully follow applicable State and federal laws, Illinois can minimize the pernicious problems other states are going to face from the uncontrolled release of radioactive elements into their water and soil and work and non-work settings. We should prevent these problem from the start. Cleanup, after the oil and gas industry is gone, will be dreadfully expensive.. Recommendations: 1. Define the test date as = Day 21, the point at which increases in test results begin to level off. 2. Test for "radioactivity" in (1) flowback/produced water, (2) drill cuttings, soil "adjacent to" (3) storage tanks and (4) reserve pits, and (5) pipes and well pad equipment. 3. Define "adjacent to" as between 6 and 12 inches with test samples to be taken within the top 6 inches of soil 4. The rules should also require that the requirements of the Illinois Low Level Radioactivity Waste Management Act be followed.

Sincerely, Paulo Nacimiento Chicago, IL 60637

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Act §1-75(a)7 requires radioactivity testing "once per well site" for (1) flowback water and ground "adjacent to" (2) storage tanks and (3) reserve pits. Act § 1-120 requires IDNR compliance with all "applicable federal, State, and local laws." One applicable State law is the Illinois Low-Level Radioactive Waste Management Act (PA 83-991 / 420ILCS20). Another is the Occupational Health and Safety Administration (OSHA) standards for workplace safety in settings with exposure to radioactivity (29 CFR 1910.1096). Rules §245.850(d)1-E and §245.850(e) are incomplete and deficient, and these inadequacies can "constitute a serious threat"--indeed, deadly threat-- "to the public interest, safety, or welfare" of Illinois citizens." Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Notably absent from these proposed rules is a requirement for the testing of "produced water", the fluid that returns from the well during the later stage of production (after flowback). Under the proposed rules, "produced water" can be stored on site and/or can be "recycled", yet there is no testing requirement. Naturally occurring radioactive material (NORM) is found in "produced water" also. See Technologically enhanced naturally occurring radioactive materials in the oil industry (TENORM), Nukleonika 2009; 54(1):3-9, and sources cited therein, especially for TENORM in produced water in the U.S., available at [http://www.nukleonika.pl/www/back/full/vol54\\_2009/v54n1p003f.pdf](http://www.nukleonika.pl/www/back/full/vol54_2009/v54n1p003f.pdf). See also NORM is also found on scale in oil pipes and on fracking equipment. (See Kentucky Resources Council Proposes Comprehensive Plan For Investigating Radiological Contamination In Martha Oil Field. August 11, 2005. <http://www.kyrc.org/webnewspro/112381723236086.shtml>.) IDNR's definitions of "flowback water" and "produced water" are different. The two are distinguishably different enough that they are treated as separate types of fluid by both the Hydraulic Fracturing Regulatory Act and by the DNR Rules. Discharge of produced water onto the ground or into surface water or water drainage way is prohibited but it is not tested for radioactivity. This despite the fact that this fluid will be in contact with the naturally occurring radioactive elements in the ground for a longer period than the flowback and that it is much more likely to be radioactive. Problems: Failure to test produced water for radioactivity is problematic for a variety of reasons including: The health and safety of workers on the site who will be unaware of the levels of radioactivity they are being exposed to. The health and safety of workers transporting produced water who will also be in the dark regarding the levels of radioactivity they will be exposed to. The risk of storing radioactive material in tanks not created for storing radioactive materials. The risk of "recycling" produced water—radioactivity cannot be removed by recycling. The risk to the public in transporting radioactive materials Argonne National Laboratory recently cautioned about radiological doses: "It is commonly accepted that efforts should be undertaken at all times to keep radiological doses 'as low as reasonably achievable,' which is referred to as the ALARA principle or requirement." Overview of Radiological Dose and Risk Assessment (April 2011). DNR is failing to even adequately test for radioactivity and therefore, will not know the levels of radioactivity. How, then, can

## Fair Economy Illinois

---

DNR adequately protect workers and the general public? Elaboration: IDNR does not define a Fixed Date ( $\pm X$  days) for testing. Day 1, <Hour 1 test results will be orders of magnitude lower than either Day 2 or Day 10 tests results, and Day 10 tests results will be significantly lower than Day 80 ( $\pm 7$  days) results. Failure to specify a Fixed Test Date ( $\pm X$  days) renders test data so many irrelevant apples and oranges and allows companies to report suppressed, meaningless results by reporting Day 1, < 1 Hour data. The figure below, provided by the USGS, illustrates the nature of the problem. Please note that radium is not tested at Day 1, < 1 Hour. However, radium coprecipitates with barium, which is represented in total dissolved solids (TDS). It will therefore track TDS fairly closely. Conclusion: companies will be testing the very first flowback water to emerge from a fracked well. It will be Day 1, Minute 1 test results. 2.) There are two pits on a frack pad, one for "emergency" flowback and another, smaller one for drill cuttings and drilling mud. It is a basic principle in horizontal fracking to steer the drill bit through the horizontal strata with the highest gamma radiation readings (GAPI logs). The reason is that radioactivity correlates highly with total organic content (TOC) in the rock, and TOC correlates highly with oil and gas yields. This means that rock cuttings in the smaller drill mud and cuttings frack pit will often be more radioactive than flowback water. The IDNR knows this; yet it does not call for testing of drill bit pits as allowed under the Powers and duties section of the Act (§1- 15). 3.) The term "adjacent to" requires a "precise, clear standard" [IAPA, §100/5-20]. None is given. Does "adjacent to" mean 6 inches, 16 inches, 6 feet, 16 feet, or 60 feet? The IDNR does not say. 4.) Frack pad pipes and equipment can become incredibly radioactive over time. The very large temperature and pressure drops, as fluids move to the surface from thousands of feet underground, means that aqueous radioactive salts precipitate out as scale on pipes and equipment. The levels of radioactivity in pipe scale can exceed 100,000 picoCuries per gram and constitute a hazard to workers, or others who are exposed to recycled scrap metal from gas and oil operations. Yet, IDNR does not call on its General Assembly deferred "Power and authority" [Act, §1-15(e)] to test pipe, tanks, sludge, and equipment. This issue has been an issue in the oil and gas industry since the 1980s. We should prevent these problem from the start. Cleanup, after the oil and gas industry is gone, will be dreadfully expensive.. Recommendations: 1. Define the test date as = Day 21, the point at which increases in test results begin to level off. 2. Test for "radioactivity" in (1) flowback/produced water, (2) drill cuttings, soil "adjacent to" (3) storage tanks and (4) reserve pits, and (5) pipes and well pad equipment. 3. Define "adjacent to" as between 6 and 12 inches with test samples to be taken within the top 6 inches of soil 4. The rules should also require that the requirements of the Illinois Low Level Radioactivity Waste Management Act be followed.

Sincerely, Rachel Pinker Chicago, IL 60637

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Act §1-75(a)7 requires radioactivity testing "once per well site" for (1) flowback water and ground "adjacent to" (2) storage tanks and (3) reserve pits. Act § 1-120 requires IDNR compliance with all "applicable federal, State, and local laws." One applicable State law is the Illinois Low-Level Radioactive Waste Management Act (PA 83-991 / 420ILCS20). Another is the Occupational Health and Safety Administration (OSHA) standards for workplace safety in settings with exposure to radioactivity (29 CFR 1910.1096). Rules §245.850(d)1-E and §245.850(e) are incomplete and deficient, and these inadequacies can "constitute a serious threat"--indeed, deadly threat-- "to the public interest, safety, or welfare" of Illinois citizens." Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Notably absent from these proposed rules is a requirement for the testing of "produced water", the fluid that returns from the well during the later stage of production (after flowback). Under the proposed rules, "produced water" can be stored on site and/or can be "recycled", yet there is no testing requirement. Naturally occurring radioactive material (NORM) is found in "produced water" also. See Technologically enhanced naturally occurring radioactive materials in the oil industry (TENORM), Nukleonika 2009; 54(1):3-9, and sources cited therein, especially for TENORM in produced water in the U.S., available at [http://www.nukleonika.pl/www/back/full/vol54\\_2009/v54n1p003f.pdf](http://www.nukleonika.pl/www/back/full/vol54_2009/v54n1p003f.pdf). See also NORM is also found on scale in oil pipes and on fracking equipment. (See Kentucky Resources Council Proposes Comprehensive Plan For Investigating Radiological Contamination In Martha Oil Field. August 11, 2005. <http://www.kyrc.org/webnewspro/112381723236086.shtml>.) IDNR's definitions of "flowback water" and "produced water" are different. The two are distinguishably different enough that they are treated as separate types of fluid by both the Hydraulic Fracturing Regulatory Act and by the DNR Rules. Discharge of produced water onto the ground or into surface water or water drainage way is prohibited but it is not tested for radioactivity. This despite the fact that this fluid will be in contact with the naturally occurring radioactive elements in the ground for a longer period than the flowback and that it is much more likely to be radioactive. Problems: Failure to test produced water for radioactivity is problematic for a variety of reasons including: The health and safety of workers on the site who will be unaware of the levels of radioactivity they are being exposed to. The health and safety of workers transporting produced water who will also be in the dark regarding the levels of radioactivity they will be exposed to. The risk of storing radioactive material in tanks not created for storing radioactive materials. The risk of "recycling" produced water—radioactivity cannot be removed by recycling. The risk to the public in transporting radioactive materials Argonne National Laboratory recently cautioned about radiological doses: "It is commonly accepted that efforts should be undertaken at all times to keep radiological doses 'as low as reasonably achievable,' which is referred to as the ALARA principle or requirement." Overview of Radiological Dose and Risk Assessment (April 2011). DNR is failing to even adequately test for radioactivity and therefore, will not know the levels of radioactivity. How, then, can

## Fair Economy Illinois

---

DNR adequately protect workers and the general public? Elaboration: IDNR does not define a Fixed Date ( $\pm X$  days) for testing. Day 1, <Hour 1 test results will be orders of magnitude lower than either Day 2 or Day 10 tests results, and Day 10 tests results will be significantly lower than Day 80 ( $\pm 7$  days) results. Failure to specify a Fixed Test Date ( $\pm X$  days) renders test data so many irrelevant apples and oranges and allows companies to report suppressed, meaningless results by reporting Day 1, < 1 Hour data. The figure below, provided by the USGS, illustrates the nature of the problem. Please note that radium is not tested at Day 1, < 1 Hour. However, radium coprecipitates with barium, which is represented in total dissolved solids (TDS). It will therefore track TDS fairly closely. Conclusion: companies will be testing the very first flowback water to emerge from a fracked well. It will be Day 1, Minute 1 test results. 2.) There are two pits on a frack pad, one for "emergency" flowback and another, smaller one for drill cuttings and drilling mud. It is a basic principle in horizontal fracking to steer the drill bit through the horizontal strata with the highest gamma radiation readings (GAPI logs). The reason is that radioactivity correlates highly with total organic content (TOC) in the rock, and TOC correlates highly with oil and gas yields. This means that rock cuttings in the smaller drill mud and cuttings frack pit will often be more radioactive than flowback water. The IDNR knows this; yet it does not call for testing of drill bit pits as allowed under the Powers and duties section of the Act (§1- 15). 3.) The term "adjacent to" requires a "precise, clear standard" [IAPA, §100/5-20]. None is given. Does "adjacent to" mean 6 inches, 16 inches, 6 feet, 16 feet, or 60 feet? The IDNR does not say. 4.) Frack pad pipes and equipment can become incredibly radioactive over time. The very large temperature and pressure drops, as fluids move to the surface from thousands of feet underground, means that aqueous radioactive salts precipitate out as scale on pipes and equipment. The levels of radioactivity in pipe scale can exceed 100,000 picoCuries per gram and constitute a hazard to workers, or others who are exposed to recycled scrap metal from gas and oil operations. Yet, IDNR does not call on its General Assembly deferred "Power and authority" [Act, §1-15(e)] to test pipe, tanks, sludge, and equipment. This issue has been an issue in the oil and gas industry since the 1980s. Consequences: According to studies by the Illinois State Geological Survey, the Illinois New Albany Shale Formation, the source rock for our oil and gas reserves, has above average levels of uranium (29 ppm). Uranium decays into radium and thence radon. Both uranium and radium are water soluble. As noted, the U.S. Geological Survey has found oil field brine or produced water in Southern Illinois to have Radium226 levels that average more than 1,000 picoCuries / liter (USGS 1999). That reading is 67 times above the maximum contamination level of the EPA. Radium226 has a half life of 1,600 years. Uranium228 has a half life of 4.468 billion years. If these water soluble salts leach into our aquifers, nearby communities will require--if possible--very expensive water treatment for the next 1,000 years. We may have to return to rainwater harvesting with the modern equivalent of cisterns. The radioactive levels for produced water from shale gas operations are likely to be 2 to 4 times higher than oilfield brine -- on average, 2,000 to 4,000 picoCuries per liter. In addition, radon levels in methane, propane, and ethane can be dangerously high. When it becomes commercial to extract shale gas from the SE corner of the state, major markets, such as Springfield and Chicago, will only be 0.9 and 1.4 days removed from shale gas wellheads. Even though radon222 has a half life of only 3.8 days, the closeness of major Illinois retail gas markets will mean that large number of people will be breathing in high levels of radon when they cook meals. The average level of indoor exposure to radon in Illinois is already 4.4

## Fair Economy Illinois

---

pCi/L ( American Lung Association 2013). The EPA maximum level--the point at which corrective action should be taken--is 4.0 pCi/L, and the preferred level is =3.0 pCi/L. The turn to shale gas, with its high levels of radon, will also turn a major Illinois public health problem in the wrong direction. Radioactive scale in pipe and equipment presents another problem; high levels of radioactivity have been found in school playground equipment and bleachers in school sports stadiums in Mississippi and Texas. Do we want untested oil and gas field scrap metal sold into Illinois markets? Do we want our children exposed on a daily basis to radioactive metal? The present rules creates no barriers to such an outcome. The problems cited above are why Illinois, with its large number of nuclear power plants, has a Low-Level Radioactive Waste Management Act. It and OSHA are the applicable State and Federal agencies with respect to the issue of radioactive waste and work safety standards in settings with exposure to radioactivity. If we faithfully follow applicable State and federal laws, Illinois can minimize the pernicious problems other states are going to face from the uncontrolled release of radioactive elements into their water and soil and work and non-work settings. We should prevent these problem from the start. Cleanup, after the oil and gas industry is gone, will be dreadfully expensive.. Recommendations: 1. Define the test date as = Day 21, the point at which increases in test results begin to level off. 2. Test for "radioactivity" in (1) flowback/produced water, (2) drill cuttings, soil "adjacent to" (3) storage tanks and (4) reserve pits, and (5) pipes and well pad equipment. 3. Define "adjacent to" as between 6 and 12 inches with test samples to be taken within the top 6 inches of soil 4. In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Act §1-75(a)7 requires radioactivity testing "once per well site" for (1) flowback water and ground "adjacent to" (2) storage tanks and (3) reserve pits. Act § 1-120 requires IDNR compliance with all "applicable federal, State, and local laws." One applicable State law is the Illinois Low-Level Radioactive Waste Management Act (PA 83-991 / 420ILCS20). Another is the Occupational Health and Safety Administration (OSHA) standards for workplace safety in settings with exposure to radioactivity (29 CFR 1910.1096). Rules §245.850(d)1-E and §245.850(e) are incomplete and deficient, and these inadequacies can "constitute a serious threat"--indeed, deadly threat-- "to the public interest, safety, or welfare" of Illinois citizens." Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Notably absent from these proposed rules is a requirement for the testing of "produced water", the fluid that returns from the well during the later stage of production (after flowback). Under the proposed rules, "produced water" can be stored on site and/or can be "recycled", yet there is no testing requirement. Naturally occurring radioactive material (NORM) is found in "produced water" also. See Technologically enhanced naturally occurring radioactive materials in the oil industry (TENORM), Nukleonika 2009; 54(1):3-9, and sources cited therein, especially for TENORM in produced water in the U.S., available at [http://www.nukleonika.pl/www/back/full/vol54\\_2009/v54n1p003f.pdf](http://www.nukleonika.pl/www/back/full/vol54_2009/v54n1p003f.pdf). See also NORM is also found on scale in oil pipes and on fracking equipment. (See Kentucky Resources Council Proposes Comprehensive Plan For Investigating Radiological Contamination In Martha Oil Field. August 11, 2005. <http://www.kyrc.org/webnewspro/112381723236086.shtml>.) IDNR's definitions of "flowback water" and "produced water" are different. The two are distinguishably different enough that they are treated as separate types of fluid by both the Hydraulic Fracturing Regulatory Act and by the DNR Rules. Discharge of produced water onto the ground or into surface water or water drainage way is prohibited but it is not tested for radioactivity. This despite the fact that this fluid will be in contact with the naturally occurring radioactive elements in the ground for a longer period than the flowback and that it is much more likely to be radioactive. Problems: Failure to test produced water for radioactivity is problematic for a variety of reasons including: The health and safety of workers on the site who will be unaware of the levels of radioactivity they are being exposed to. The health and safety of workers transporting produced water who will also be in the dark regarding the levels of radioactivity they will be exposed to. The risk of storing radioactive material in tanks not created for storing radioactive materials. The risk of "recycling" produced water—radioactivity cannot be removed by recycling. The risk to the public in transporting radioactive materials Argonne National Laboratory recently cautioned about radiological doses: "It is commonly accepted that efforts should be undertaken at all times to keep radiological doses 'as low as reasonably achievable,' which is referred to as the ALARA principle or requirement." Overview of Radiological Dose and Risk Assessment (April 2011). DNR is failing to even adequately test for radioactivity and therefore, will not know the levels of radioactivity. How, then, can

## Fair Economy Illinois

---

DNR adequately protect workers and the general public? Elaboration: IDNR does not define a Fixed Date ( $\pm X$  days) for testing. Day 1, <Hour 1 test results will be orders of magnitude lower than either Day 2 or Day 10 tests results, and Day 10 tests results will be significantly lower than Day 80 ( $\pm 7$  days) results. Failure to specify a Fixed Test Date ( $\pm X$  days) renders test data so many irrelevant apples and oranges and allows companies to report suppressed, meaningless results by reporting Day 1, < 1 Hour data. The figure below, provided by the USGS, illustrates the nature of the problem. Please note that radium is not tested at Day 1, < 1 Hour. However, radium coprecipitates with barium, which is represented in total dissolved solids (TDS). It will therefore track TDS fairly closely. Conclusion: companies will be testing the very first flowback water to emerge from a fracked well. It will be Day 1, Minute 1 test results. 2.) There are two pits on a frack pad, one for "emergency" flowback and another, smaller one for drill cuttings and drilling mud. It is a basic principle in horizontal fracking to steer the drill bit through the horizontal strata with the highest gamma radiation readings (GAPI logs). The reason is that radioactivity correlates highly with total organic content (TOC) in the rock, and TOC correlates highly with oil and gas yields. This means that rock cuttings in the smaller drill mud and cuttings frack pit will often be more radioactive than flowback water. The IDNR knows this; yet it does not call for testing of drill bit pits as allowed under the Powers and duties section of the Act (§1- 15). 3.) The term "adjacent to" requires a "precise, clear standard" [IAPA, §100/5-20]. None is given. Does "adjacent to" mean 6 inches, 16 inches, 6 feet, 16 feet, or 60 feet? The IDNR does not say. 4.) Frack pad pipes and equipment can become incredibly radioactive over time. The very large temperature and pressure drops, as fluids move to the surface from thousands of feet underground, means that aqueous radioactive salts precipitate out as scale on pipes and equipment. The levels of radioactivity in pipe scale can exceed 100,000 picoCuries per gram and constitute a hazard to workers, or others who are exposed to recycled scrap metal from gas and oil operations. Yet, IDNR does not call on its General Assembly deferred "Power and authority" [Act, §1-15(e)] to test pipe, tanks, sludge, and equipment. This issue has been an issue in the oil and gas industry since the 1980s. Consequences: According to studies by the Illinois State Geological Survey, the Illinois New Albany Shale Formation, the source rock for our oil and gas reserves, has above average levels of uranium (29 ppm). Uranium decays into radium and thence radon. Both uranium and radium are water soluble. As noted, the U.S. Geological Survey has found oil field brine or produced water in Southern Illinois to have Radium226 levels that average more than 1,000 picoCuries / liter (USGS 1999). That reading is 67 times above the maximum contamination level of the EPA. Radium226 has a half life of 1,600 years. Uranium228 has a half life of 4.468 billion years. If these water soluble salts leach into our aquifers, nearby communities will require--if possible--very expensive water treatment for the next 1,000 years. We may have to return to rainwater harvesting with the modern equivalent of cisterns. The radioactive levels for produced water from shale gas operations are likely to be 2 to 4 times higher than oilfield brine -- on average, 2,000 to 4,000 picoCuries per liter. In addition, radon levels in methane, propane, and ethane can be dangerously high. When it becomes commercial to extract shale gas from the SE corner of the state, major markets, such as Springfield and Chicago, will only be 0.9 and 1.4 days removed from shale gas wellheads. Even though radon222 has a half life of only 3.8 days, the closeness of major Illinois retail gas markets will mean that large number of people will be breathing in high levels of radon when they cook meals. The average level of indoor exposure to radon in Illinois is already 4.4

## Fair Economy Illinois

---

pCi/L ( American Lung Association 2013). The EPA maximum level--the point at which corrective action should be taken--is 4.0 pCi/L, and the preferred level is =3.0 pCi/L. The turn to shale gas, with its high levels of radon, will also turn a major Illinois public health problem in the wrong direction. Radioactive scale in pipe and equipment presents another problem; high levels of radioactivity have been found in school playground equipment and bleachers in school sports stadiums in Mississippi and Texas. Do we want untested oil and gas field scrap metal sold into Illinois markets? Do we want our children exposed on a daily basis to radioactive metal? The present rules creates no barriers to such an outcome. The problems cited above are why Illinois, with its large number of nuclear power plants, has a Low-Level Radioactive Waste Management Act. It and OSHA are the applicable State and Federal agencies with respect to the issue of radioactive waste and work safety standards in settings with exposure to radioactivity. If we faithfully follow applicable State and federal laws, Illinois can minimize the pernicious problems other states are going to face from the uncontrolled release of radioactive elements into their water and soil and work and non-work settings. We should prevent these problem from the start. Cleanup, after the oil and gas industry is gone, will be dreadfully expensive.. Recommendations: 1. Define the test date as = Day 21, the point at which increases in test results begin to level off. 2. Test for "radioactivity" in (1) flowback/produced water, (2) drill cuttings, soil "adjacent to" (3) storage tanks and (4) reserve pits, and (5) pipes and well pad equipment. 3. Define "adjacent to" as between 6 and 12 inches with test samples to be taken within the top 6 inches of soil 4. The rules should also require that the requirements of the Illinois Low Level Radioactivity Waste Management Act be followed.

Sincerely, Rachelle Ankney Chicago, IL 60626

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Act §1-75(a)7 requires radioactivity testing "once per well site" for (1) flowback water and ground "adjacent to" (2) storage tanks and (3) reserve pits. Act § 1-120 requires IDNR compliance with all "applicable federal, State, and local laws." One applicable State law is the Illinois Low-Level Radioactive Waste Management Act (PA 83-991 / 420ILCS20). Another is the Occupational Health and Safety Administration (OSHA) standards for workplace safety in settings with exposure to radioactivity (29 CFR 1910.1096). Rules §245.850(d)1-E and §245.850(e) are incomplete and deficient, and these inadequacies can "constitute a serious threat"--indeed, deadly threat-- "to the public interest, safety, or welfare" of Illinois citizens." Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Notably absent from these proposed rules is a requirement for the testing of "produced water", the fluid that returns from the well during the later stage of production (after flowback). Under the proposed rules, "produced water" can be stored on site and/or can be "recycled", yet there is no testing requirement. Naturally occurring radioactive material (NORM) is found in "produced water" also. See Technologically enhanced naturally occurring radioactive materials in the oil industry (TENORM), Nukleonika 2009; 54(1):3-9, and sources cited therein, especially for TENORM in produced water in the U.S., available at [http://www.nukleonika.pl/www/back/full/vol54\\_2009/v54n1p003f.pdf](http://www.nukleonika.pl/www/back/full/vol54_2009/v54n1p003f.pdf). See also NORM is also found on scale in oil pipes and on fracking equipment. (See Kentucky Resources Council Proposes Comprehensive Plan For Investigating Radiological Contamination In Martha Oil Field. August 11, 2005. <http://www.kyrc.org/webnewspro/112381723236086.shtml>.) IDNR's definitions of "flowback water" and "produced water" are different. In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Act §1-75(a)7 requires radioactivity testing "once per well site" for (1) flowback water and ground "adjacent to" (2) storage tanks and (3) reserve pits. Act § 1-120 requires IDNR compliance with all "applicable federal, State, and local laws." One applicable State law is the Illinois Low-Level Radioactive Waste Management Act (PA 83-991 / 420ILCS20). Another is the Occupational Health and Safety Administration (OSHA) standards for workplace safety in settings with exposure to radioactivity (29 CFR 1910.1096). Rules §245.850(d)1-E and §245.850(e) are incomplete and deficient, and these inadequacies can "constitute a serious threat"--indeed, deadly threat-- "to the public interest, safety, or welfare" of Illinois citizens." Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Notably absent from these proposed rules is a requirement for the testing of "produced water", the fluid that returns from the well during the later stage of production (after flowback). Under the proposed rules, "produced water" can be stored on site and/or can be "recycled", yet there is no testing requirement. Naturally occurring radioactive material (NORM) is found in "produced water" also. See Technologically enhanced naturally occurring radioactive materials in the oil industry (TENORM), Nukleonika 2009; 54(1):3-9, and sources cited therein, especially for TENORM in produced water in the U.S., available at [http://www.nukleonika.pl/www/back/full/vol54\\_2009/v54n1p003f.pdf](http://www.nukleonika.pl/www/back/full/vol54_2009/v54n1p003f.pdf). See also NORM is also found on scale in oil pipes and on fracking equipment. (See Kentucky Resources Council Proposes Comprehensive Plan For Investigating Radiological Contamination In Martha Oil Field. August 11, 2005. <http://www.kyrc.org/webnewspro/112381723236086.shtml>.) IDNR's definitions of "flowback water" and "produced water" are different. The two are distinguishably different enough that they are treated as separate types of fluid by both the Hydraulic Fracturing Regulatory Act and by the DNR Rules. Discharge of produced water onto the ground or into surface water or water drainage way is prohibited but it is not tested for radioactivity. This despite the fact that this fluid will be in contact with the naturally occurring radioactive elements in the ground for a longer period than the flowback and that it is much more likely to be radioactive. Problems: Failure to test produced water for radioactivity is problematic for a variety of reasons including: The health and safety of workers on the site who will be unaware of the levels of radioactivity they are being exposed to. The health and safety of workers transporting produced water who will also be in the dark regarding the levels of radioactivity they will be exposed to. The risk of storing radioactive material in tanks not created for storing radioactive materials. The risk of "recycling" produced water—radioactivity cannot be removed by recycling. The risk to the public in transporting radioactive materials Argonne National Laboratory recently cautioned about radiological doses: "It is commonly accepted that efforts should be undertaken at all times to keep radiological doses 'as low as reasonably achievable,' which is referred to as the ALARA principle or requirement." Overview of Radiological Dose and Risk Assessment (April 2011). DNR is failing to even adequately test for radioactivity and therefore, will not know the levels of radioactivity. How, then, can

## Fair Economy Illinois

---

DNR adequately protect workers and the general public? Elaboration: IDNR does not define a Fixed Date ( $\pm X$  days) for testing. Day 1, <Hour 1 test results will be orders of magnitude lower than either Day 2 or Day 10 tests results, and Day 10 tests results will be significantly lower than Day 80 ( $\pm 7$  days) results. Failure to specify a Fixed Test Date ( $\pm X$  days) renders test data so many irrelevant apples and oranges and allows companies to report suppressed, meaningless results by reporting Day 1, < 1 Hour data. The figure below, provided by the USGS, illustrates the nature of the problem. Please note that radium is not tested at Day 1, < 1 Hour. However, radium coprecipitates with barium, which is represented in total dissolved solids (TDS). It will therefore track TDS fairly closely. Conclusion: companies will be testing the very first flowback water to emerge from a fracked well. It will be Day 1, Minute 1 test results. 2.) There are two pits on a frack pad, one for "emergency" flowback and another, smaller one for drill cuttings and drilling mud. It is a basic principle in horizontal fracking to steer the drill bit through the horizontal strata with the highest gamma radiation readings (GAPI logs). The reason is that radioactivity correlates highly with total organic content (TOC) in the rock, and TOC correlates highly with oil and gas yields. This means that rock cuttings in the smaller drill mud and cuttings frack pit will often be more radioactive than flowback water. The IDNR knows this; yet it does not call for testing of drill bit pits as allowed under the Powers and duties section of the Act (§1- 15). 3.) The term "adjacent to" requires a "precise, clear standard" [IAPA, §100/5-20]. None is given. Does "adjacent to" mean 6 inches, 16 inches, 6 feet, 16 feet, or 60 feet? The IDNR does not say. 4.) Frack pad pipes and equipment can become incredibly radioactive over time. The very large temperature and pressure drops, as fluids move to the surface from thousands of feet underground, means that aqueous radioactive salts precipitate out as scale on pipes and equipment. The levels of radioactivity in pipe scale can exceed 100,000 picoCuries per gram and constitute a hazard to workers, or others who are exposed to recycled scrap metal from gas and oil operations. Yet, IDNR does not call on its General Assembly deferred "Power and authority" [Act, §1-15(e)] to test pipe, tanks, sludge, and equipment. This issue has been an issue in the oil and gas industry since the 1980s. Consequences: According to studies by the Illinois State Geological Survey, the Illinois New Albany Shale Formation, the source rock for our oil and gas reserves, has above average levels of uranium (29 ppm). Uranium decays into radium and thence radon. Both uranium and radium are water soluble. As noted, the U.S. Geological Survey has found oil field brine or produced water in Southern Illinois to have Radium226 levels that average more than 1,000 picoCuries / liter (USGS 1999). That reading is 67 times above the maximum contamination level of the EPA. Radium226 has a half life of 1,600 years. Uranium228 has a half life of 4.468 billion years. If these water soluble salts leach into our aquifers, nearby communities will require--if possible--very expensive water treatment for the next 1,000 years. We may have to return to rainwater harvesting with the modern equivalent of cisterns. The radioactive levels for produced water from shale gas operations are likely to be 2 to 4 times higher than oilfield brine -- on average, 2,000 to 4,000 picoCuries per liter. In addition, radon levels in methane, propane, and ethane can be dangerously high. When it becomes commercial to extract shale gas from the SE corner of the state, major markets, such as Springfield and Chicago, will only be 0.9 and 1.4 days removed from shale gas wellheads. Even though radon222 has a half life of only 3.8 days, the closeness of major Illinois retail gas markets will mean that large number of people will be breathing in high levels of radon when they cook meals. The average level of indoor exposure to radon in Illinois is already 4.4

## Fair Economy Illinois

---

pCi/L ( American Lung Association 2013). The EPA maximum level--the point at which corrective action should be taken--is 4.0 pCi/L, and the preferred level is =3.0 pCi/L. The turn to shale gas, with its high levels of radon, will also turn a major Illinois public health problem in the wrong direction. Radioactive scale in pipe and equipment presents another problem; high levels of radioactivity have been found in school playground equipment and bleachers in school sports stadiums in Mississippi and Texas. Do we want untested oil and gas field scrap metal sold into Illinois markets? Do we want our children exposed on a daily basis to radioactive metal? The present rules creates no barriers to such an outcome. The problems cited above are why Illinois, with its large number of nuclear power plants, has a Low-Level Radioactive Waste Management Act. It and OSHA are the applicable State and Federal agencies with respect to the issue of radioactive waste and work safety standards in settings with exposure to radioactivity. If we faithfully follow applicable State and federal laws, Illinois can minimize the pernicious problems other states are going to face from the uncontrolled release of radioactive elements into their water and soil and work and non-work settings. We should prevent these problem from the start. Cleanup, after the oil and gas industry is gone, will be dreadfully expensive.. Recommendations: 1. Define the test date as = Day 21, the point at which increases in test results begin to level off. 2. Test for "radioactivity" in (1) flowback/produced water, (2) drill cuttings, soil "adjacent to" (3) storage tanks and (4) reserve pits, and (5) pipes and well pad equipment. 3. Define "adjacent to" as between 6 and 12 inches with test samples to be taken within the top 6 inches of soil 4. The rules should also require that the requirements of the Illinois Low Level Radioactivity Waste Management Act be followed.

Sincerely, Rebekah Sugarman Syosset, IL 11791

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Act §1-75(a)7 requires radioactivity testing "once per well site" for (1) flowback water and ground "adjacent to" (2) storage tanks and (3) reserve pits. Act § 1-120 requires IDNR compliance with all "applicable federal, State, and local laws." One applicable State law is the Illinois Low-Level Radioactive Waste Management Act (PA 83-991 / 420ILCS20). Another is the Occupational Health and Safety Administration (OSHA) standards for workplace safety in settings with exposure to radioactivity (29 CFR 1910.1096). Rules §245.850(d)1-E and §245.850(e) are incomplete and deficient, and these inadequacies can "constitute a serious threat"--indeed, deadly threat-- "to the public interest, safety, or welfare" of Illinois citizens." Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Notably absent from these proposed rules is a requirement for the testing of "produced water", the fluid that returns from the well during the later stage of production (after flowback). Under the proposed rules, "produced water" can be stored on site and/or can be "recycled", yet there is no testing requirement. Naturally occurring radioactive material (NORM) is found in "produced water" also. See Technologically enhanced naturally occurring radioactive materials in the oil industry (TENORM), Nukleonika 2009; 54(1):3-9, and sources cited therein, especially for TENORM in produced water in the U.S., available at [http://www.nukleonika.pl/www/back/full/vol54\\_2009/v54n1p003f.pdf](http://www.nukleonika.pl/www/back/full/vol54_2009/v54n1p003f.pdf). See also NORM is also found on scale in oil pipes and on fracking equipment. (See Kentucky Resources Council Proposes Comprehensive Plan For Investigating Radiological Contamination In Martha Oil Field. August 11, 2005. <http://www.kyrc.org/webnewspro/112381723236086.shtml>.) IDNR's definitions of "flowback water" and "produced water" are different. The two are distinguishably different enough that they are treated as separate types of fluid by both the Hydraulic Fracturing Regulatory Act and by the DNR Rules. Discharge of produced water onto the ground or into surface water or water drainage way is prohibited but it is not tested for radioactivity. This despite the fact that this fluid will be in contact with the naturally occurring radioactive elements in the ground for a longer period than the flowback and that it is much more likely to be radioactive. Problems: Failure to test produced water for radioactivity is problematic for a variety of reasons including: The health and safety of workers on the site who will be unaware of the levels of radioactivity they are being exposed to. The health and safety of workers transporting produced water who will also be in the dark regarding the levels of radioactivity they will be exposed to. The risk of storing radioactive material in tanks not created for storing radioactive materials. The risk of "recycling" produced water—radioactivity cannot be removed by recycling. The risk to the public in transporting radioactive materials Argonne National Laboratory recently cautioned about radiological doses: "It is commonly accepted that efforts should be undertaken at all times to keep radiological doses 'as low as reasonably achievable,' which is referred to as the ALARA principle or requirement." Overview of Radiological Dose and Risk Assessment (April 2011). DNR is failing to even adequately test for radioactivity and therefore, will not know the levels of radioactivity. How, then, can

## Fair Economy Illinois

---

DNR adequately protect workers and the general public? Elaboration: IDNR does not define a Fixed Date ( $\pm X$  days) for testing. Day 1, <Hour 1 test results will be orders of magnitude lower than either Day 2 or Day 10 tests results, and Day 10 tests results will be significantly lower than Day 80 ( $\pm 7$  days) results. Failure to specify a Fixed Test Date ( $\pm X$  days) renders test data so many irrelevant apples and oranges and allows companies to report suppressed, meaningless results by reporting Day 1, < 1 Hour data. The figure below, provided by the USGS, illustrates the nature of the problem. Please note that radium is not tested at Day 1, < 1 Hour. However, radium coprecipitates with barium, which is represented in total dissolved solids (TDS). It will therefore track TDS fairly closely. Conclusion: companies will be testing the very first flowback water to emerge from a fracked well. It will be Day 1, Minute 1 test results. 2.) There are two pits on a frack pad, one for "emergency" flowback and another, smaller one for drill cuttings and drilling mud. It is a basic principle in horizontal fracking to steer the drill bit through the horizontal strata with the highest gamma radiation readings (GAPI logs). The reason is that radioactivity correlates highly with total organic content (TOC) in the rock, and TOC correlates highly with oil and gas yields. This means that rock cuttings in the smaller drill mud and cuttings frack pit will often be more radioactive than flowback water. The IDNR knows this; yet it does not call for testing of drill bit pits as allowed under the Powers and duties section of the Act (§1- 15). 3.) The term "adjacent to" requires a "precise, clear standard" [IAPA, §100/5-20]. None is given. Does "adjacent to" mean 6 inches, 16 inches, 6 feet, 16 feet, or 60 feet? The IDNR does not say. 4.) Frack pad pipes and equipment can become incredibly radioactive over time. pCi/L ( American Lung Association 2013). The EPA maximum level--the point at which corrective action should be taken--is 4.0 pCi/L, and the preferred level is =3.0 pCi/L. The turn to shale gas, with its high levels of radon, will also turn a major Illinois public health problem in the wrong direction. Radioactive scale in pipe and equipment presents another problem; high levels of radioactivity have been found in school playground equipment and bleachers in school sports stadiums in Mississippi and Texas. Do we want untested oil and gas field scrap metal sold into Illinois markets? Do we want our children exposed on a daily basis to radioactive metal? The present rules creates no barriers to such an outcome. The problems cited above are why Illinois, with its large number of nuclear power plants, has a Low-Level Radioactive Waste Management Act. It and OSHA are the applicable State and Federal agencies with respect to the issue of radioactive waste and work safety standards in settings with exposure to radioactivity. If we faithfully follow applicable State and federal laws, Illinois can minimize the pernicious problems other states are going to face from the uncontrolled release of radioactive elements into their water and soil and work and non-work settings. We should prevent these problem from the start. Cleanup, after the oil and gas industry is gone, will be dreadfully expensive.. Recommendations: 1. Define the test date as = Day 21, the point at which increases in test results begin to level off. 2. Test for "radioactivity" in (1) flowback/produced water, (2) drill cuttings, soil "adjacent to" (3) storage tanks and (4) reserve pits, and (5) pipes and well pad equipment. 3. Define "adjacent to" as between 6 and 12 inches with test samples to be taken within the top 6 inches of soil 4. The rules should also require that the requirements of the Illinois Low Level Radioactivity Waste Management Act be followed.

Sincerely, Ryan Kidman Chicago, IL 60637

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Act §1-75(a)7 requires radioactivity testing "once per well site" for (1) flowback water and ground "adjacent to" (2) storage tanks and (3) reserve pits. Act § 1-120 requires IDNR compliance with all "applicable federal, State, and local laws." One applicable State law is the Illinois Low-Level Radioactive Waste Management Act (PA 83-991 / 420ILCS20). Another is the Occupational Health and Safety Administration (OSHA) standards for workplace safety in settings with exposure to radioactivity (29 CFR 1910.1096). Rules §245.850(d)1-E and §245.850(e) are incomplete and deficient, and these inadequacies can "constitute a serious threat"--indeed, deadly threat-- "to the public interest, safety, or welfare" of Illinois citizens." Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Notably absent from these proposed rules is a requirement for the testing of "produced water", the fluid that returns from the well during the later stage of production (after flowback). Under the proposed rules, "produced water" can be stored on site and/or can be "recycled", yet there is no testing requirement. Naturally occurring radioactive material (NORM) is found in "produced water" also. See Technologically enhanced naturally occurring radioactive materials in the oil industry (TENORM), Nukleonika 2009; 54(1):3-9, and sources cited therein, especially for TENORM in produced water in the U.S., available at [http://www.nukleonika.pl/www/back/full/vol54\\_2009/v54n1p003f.pdf](http://www.nukleonika.pl/www/back/full/vol54_2009/v54n1p003f.pdf). See also NORM is also found on scale in oil pipes and on fracking equipment. (See Kentucky Resources Council Proposes Comprehensive Plan For Investigating Radiological Contamination In Martha Oil Field. August 11, 2005. <http://www.kyrc.org/webnewspro/112381723236086.shtml>.) IDNR's definitions of "flowback water" and "produced water" are different. The two are distinguishably different enough that they are treated as separate types of fluid by both the Hydraulic Fracturing Regulatory Act and by the DNR Rules. Discharge of produced water onto the ground or into surface water or water drainage way is prohibited but it is not tested for radioactivity. This despite the fact that this fluid will be in contact with the naturally occurring radioactive elements in the ground for a longer period than the flowback and that it is much more likely to be radioactive. Problems: Failure to test produced water for radioactivity is problematic for a variety of reasons including: The health and safety of workers on the site who will be unaware of the levels of radioactivity they are being exposed to. The health and safety of workers transporting produced water who will also be in the dark regarding the levels of radioactivity they will be exposed to. The risk of storing radioactive material in tanks not created for storing radioactive materials. The risk of "recycling" produced water—radioactivity cannot be removed by recycling. The risk to the public in transporting radioactive materials Argonne National Laboratory recently cautioned about radiological doses: "It is commonly accepted that efforts should be undertaken at all times to keep radiological doses 'as low as reasonably achievable,' which is referred to as the ALARA principle or requirement." Overview of Radiological Dose and Risk Assessment (April 2011). DNR is failing to even adequately test for radioactivity and therefore, will not know the levels of radioactivity. How, then, can

## Fair Economy Illinois

---

DNR adequately protect workers and the general public? Elaboration: IDNR does not define a Fixed Date ( $\pm X$  days) for testing. Day 1, <Hour 1 test results will be orders of magnitude lower than either Day 2 or Day 10 tests results, and Day 10 tests results will be significantly lower than Day 80 ( $\pm 7$  days) results. Failure to specify a Fixed Test Date ( $\pm X$  days) renders test data so many irrelevant apples and oranges and allows companies to report suppressed, meaningless results by reporting Day 1, < 1 Hour data. The figure below, provided by the USGS, illustrates the nature of the problem. Please note that radium is not tested at Day 1, < 1 Hour. However, radium coprecipitates with barium, which is represented in total dissolved solids (TDS). It will therefore track TDS fairly closely. Conclusion: companies will be testing the very first flowback water to emerge from a fracked well. It will be Day 1, Minute 1 test results. 2.) There are two pits on a frack pad, one for "emergency" flowback and another, smaller one for drill cuttings and drilling mud. It is a basic principle in horizontal fracking to steer the drill bit through the horizontal strata with the highest gamma radiation readings (GAPI logs). The reason is that radioactivity correlates highly with total organic content (TOC) in the rock, and TOC correlates highly with oil and gas yields. This means that rock cuttings in the smaller drill mud and cuttings frack pit will often be more radioactive than flowback water. The IDNR knows this; yet it does not call for testing of drill bit pits as allowed under the Powers and duties section of the Act (§1- 15). 3.) The term "adjacent to" requires a "precise, clear standard" [IAPA, §100/5-20]. None is given. Does "adjacent to" mean 6 inches, 16 inches, 6 feet, 16 feet, or 60 feet? The IDNR does not say. 4.) Frack pad pipes and equipment can become incredibly radioactive over time. The very large temperature and pressure drops, as fluids move to the surface from thousands of feet underground, means that aqueous radioactive salts precipitate out as scale on pipes and equipment. The levels of radioactivity in pipe scale can exceed 100,000 picoCuries per gram and constitute a hazard to workers, or others who are exposed to recycled scrap metal from gas and oil operations. Yet, IDNR does not call on its General Assembly deferred "Power and authority" [Act, §1-15(e)] to test pipe, tanks, sludge, and equipment. This issue has been an issue in the oil and gas industry since the 1980s. Consequences: According to studies by the Illinois State Geological Survey, the Illinois New Albany Shale Formation, the source rock for our oil and gas reserves, has above average levels of uranium (29 ppm). Uranium decays into radium and thence radon. Both uranium and radium are water soluble. As noted, the U.S. Geological Survey has found oil field brine or produced water in Southern Illinois to have Radium226 levels that average more than 1,000 picoCuries / liter (USGS 1999). That reading is 67 times above the maximum contamination level of the EPA. Radium226 has a half life of 1,600 years. Uranium228 has a half life of 4.468 billion years. If these water soluble salts leach into our aquifers, nearby communities will require--if possible--very expensive water treatment for the next 1,000 years. We may have to return to rainwater harvesting with the modern equivalent of cisterns. The radioactive levels for produced water from shale gas operations are likely to be 2 to 4 times higher than oilfield brine -- on average, 2,000 to 4,000 picoCuries per liter. In addition, radon levels in methane, propane, and ethane can be dangerously high. When it becomes commercial to extract shale gas from the SE corner of the state, major markets, such as Springfield and Chicago, will only be 0.9 and 1.4 days removed from shale gas wellheads. Even though radon222 has a half life of only 3.8 days, the closeness of major Illinois retail gas markets will mean that large number of people will be breathing in high levels of radon when they cook meals. The average level of indoor exposure to radon in Illinois is already 4.4

## Fair Economy Illinois

---

pCi/L ( American Lung Association 2013). The EPA maximum level--the point at which corrective action should be taken--is 4.0 pCi/L, and the preferred level is =3.0 pCi/L. The turn to shale gas, with its high levels of radon, will also turn a major Illinois public health problem in the wrong direction. Radioactive scale in pipe and equipment presents another problem; high levels of radioactivity have been found in school playground equipment and bleachers in school sports stadiums in Mississippi and Texas. Do we want untested oil and gas field scrap metal sold into Illinois markets? Do we want our children exposed on a daily basis to radioactive metal? In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Act §1-75(a)7 requires radioactivity testing "once per well site" for (1) flowback water and ground "adjacent to" (2) storage tanks and (3) reserve pits. Act § 1-120 requires IDNR compliance with all "applicable federal, State, and local laws." One applicable State law is the Illinois Low-Level Radioactive Waste Management Act (PA 83-991 / 420ILCS20). Another is the Occupational Health and Safety Administration (OSHA) standards for workplace safety in settings with exposure to radioactivity (29 CFR 1910.1096). Rules §245.850(d)1-E and §245.850(e) are incomplete and deficient, and these inadequacies can "constitute a serious threat"--indeed, deadly threat-- "to the public interest, safety, or welfare" of Illinois citizens." Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Notably absent from these proposed rules is a requirement for the testing of "produced water", the fluid that returns from the well during the later stage of production (after flowback). Under the proposed rules, "produced water" can be stored on site and/or can be "recycled", yet there is no testing requirement. Naturally occurring radioactive material (NORM) is found in "produced water" also. See Technologically enhanced naturally occurring radioactive materials in the oil industry (TENORM), Nukleonika 2009; 54(1):3-9, and sources cited therein, especially for TENORM in produced water in the U.S., available at [http://www.nukleonika.pl/www/back/full/vol54\\_2009/v54n1p003f.pdf](http://www.nukleonika.pl/www/back/full/vol54_2009/v54n1p003f.pdf). See also NORM is also found on scale in oil pipes and on fracking equipment. (See Kentucky Resources Council Proposes Comprehensive Plan For Investigating Radiological Contamination In Martha Oil Field. August 11, 2005. <http://www.kyrc.org/webnewspro/112381723236086.shtml>.) IDNR's definitions of "flowback water" and "produced water" are different. The two are distinguishably different enough that they are treated as separate types of fluid by both the Hydraulic Fracturing Regulatory Act and by the DNR Rules. Discharge of produced water onto the ground or into surface water or water drainage way is prohibited but it is not tested for radioactivity. This despite the fact that this fluid will be in contact with the naturally occurring radioactive elements in the ground for a longer period than the flowback and that it is much more likely to be radioactive. Problems: Failure to test produced water for radioactivity is problematic for a variety of reasons including: The health and safety of workers on the site who will be unaware of the levels of radioactivity they are being exposed to. The health and safety of workers transporting produced water who will also be in the dark regarding the levels of radioactivity they will be exposed to. The risk of storing radioactive material in tanks not created for storing radioactive materials. The risk of "recycling" produced water—radioactivity cannot be removed by recycling. The risk to the public in transporting radioactive materials Argonne National Laboratory recently cautioned about radiological doses: "It is commonly accepted that efforts should be undertaken at all times to keep radiological doses 'as low as reasonably achievable,' which is referred to as the ALARA principle or requirement." Overview of Radiological Dose and Risk Assessment (April 2011). DNR is failing to even adequately test for radioactivity and therefore, will not know the levels of radioactivity. How, then, can

## Fair Economy Illinois

---

DNR adequately protect workers and the general public? Elaboration: IDNR does not define a Fixed Date ( $\pm X$  days) for testing. Day 1, <Hour 1 test results will be orders of magnitude lower than either Day 2 or Day 10 tests results, and Day 10 tests results will be significantly lower than Day 80 ( $\pm 7$  days) results. Failure to specify a Fixed Test Date ( $\pm X$  days) renders test data so many irrelevant apples and oranges and allows companies to report suppressed, meaningless results by reporting Day 1, < 1 Hour data. The figure below, provided by the USGS, illustrates the nature of the problem. Please note that radium is not tested at Day 1, < 1 Hour. However, radium coprecipitates with barium, which is represented in total dissolved solids (TDS). It will therefore track TDS fairly closely. Conclusion: companies will be testing the very first flowback water to emerge from a fracked well. It will be Day 1, Minute 1 test results. 2.) There are two pits on a frack pad, one for "emergency" flowback and another, smaller one for drill cuttings and drilling mud. It is a basic principle in horizontal fracking to steer the drill bit through the horizontal strata with the highest gamma radiation readings (GAPI logs). The reason is that radioactivity correlates highly with total organic content (TOC) in the rock, and TOC correlates highly with oil and gas yields. This means that rock cuttings in the smaller drill mud and cuttings frack pit will often be more radioactive than flowback water. The IDNR knows this; yet it does not call for testing of drill bit pits as allowed under the Powers and duties section of the Act (§1- 15). 3.) The term "adjacent to" requires a "precise, clear standard" [IAPA, §100/5-20]. None is given. Does "adjacent to" mean 6 inches, 16 inches, 6 feet, 16 feet, or 60 feet? The IDNR does not say. 4.) Frack pad pipes and equipment can become incredibly radioactive over time. The very large temperature and pressure drops, as fluids move to the surface from thousands of feet underground, means that aqueous radioactive salts precipitate out as scale on pipes and equipment. The levels of radioactivity in pipe scale can exceed 100,000 picoCuries per gram and constitute a hazard to workers, or others who are exposed to recycled scrap metal from gas and oil operations. Yet, IDNR does not call on its General Assembly deferred "Power and authority" [Act, §1-15(e)] to test pipe, tanks, sludge, and equipment. This issue has been an issue in the oil and gas industry since the 1980s. Consequences: According to studies by the Illinois State Geological Survey, the Illinois New Albany Shale Formation, the source rock for our oil and gas reserves, has above average levels of uranium (29 ppm). Uranium decays into radium and thence radon. Both uranium and radium are water soluble. As noted, the U.S. Geological Survey has found oil field brine or produced water in Southern Illinois to have Radium226 levels that average more than 1,000 picoCuries / liter (USGS 1999). That reading is 67 times above the maximum contamination level of the EPA. Radium226 has a half life of 1,600 years. Uranium228 has a half life of 4.468 billion years. If these water soluble salts leach into our aquifers, nearby communities will require--if possible--very expensive water treatment for the next 1,000 years. We may have to return to rainwater harvesting with the modern equivalent of cisterns. The radioactive levels for produced water from shale gas operations are likely to be 2 to 4 times higher than oilfield brine -- on average, 2,000 to 4,000 picoCuries per liter. In addition, radon levels in methane, propane, and ethane can be dangerously high. When it becomes commercial to extract shale gas from the SE corner of the state, major markets, such as Springfield and Chicago, will only be 0.9 and 1.4 days removed from shale gas wellheads. Even though radon222 has a half life of only 3.8 days, the closeness of major Illinois retail gas markets will mean that large number of people will be breathing in high levels of radon when they cook meals. The average level of indoor exposure to radon in Illinois is already 4.4

## Fair Economy Illinois

---

pCi/L ( American Lung Association 2013). The EPA maximum level--the point at which corrective action should be taken--is 4.0 pCi/L, and the preferred level is =3.0 pCi/L. The turn to shale gas, with its high levels of radon, will also turn a major Illinois public health problem in the wrong direction. Radioactive scale in pipe and equipment presents another problem; high levels of radioactivity have been found in school playground equipment and bleachers in school sports stadiums in Mississippi and Texas. Do we want untested oil and gas field scrap metal sold into Illinois markets? Do we want our children exposed on a daily basis to radioactive metal? The present rules creates no barriers to such an outcome. The problems cited above are why Illinois, with its large number of nuclear power plants, has a Low-Level Radioactive Waste Management Act. It and OSHA are the applicable State and Federal agencies with respect to the issue of radioactive waste and work safety standards in settings with exposure to radioactivity. If we faithfully follow applicable State and federal laws, Illinois can minimize the pernicious problems other states are going to face from the uncontrolled release of radioactive elements into their water and soil and work and non-work settings. We should prevent these problem from the start. Cleanup, after the oil and gas industry is gone, will be dreadfully expensive.. Recommendations: 1. Define the test date as = Day 21, the point at which increases in test results begin to level off. 2. Test for "radioactivity" in (1) flowback/produced water, (2) drill cuttings, soil "adjacent to" (3) storage tanks and (4) reserve pits, and (5) pipes and well pad equipment. 3. Define "adjacent to" as between 6 and 12 inches with test samples to be taken within the top 6 inches of soil 4. The rules should also require that the requirements of the Illinois Low Level Radioactivity Waste Management Act be followed.

Sincerely, Samantha Martin Chicago, IL 60605

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Act §1-75(a)7 requires radioactivity testing "once per well site" for (1) flowback water and ground "adjacent to" (2) storage tanks and (3) reserve pits. Act § 1-120 requires IDNR compliance with all "applicable federal, State, and local laws." One applicable State law is the Illinois Low-Level Radioactive Waste Management Act (PA 83-991 / 420ILCS20). Another is the Occupational Health and Safety Administration (OSHA) standards for workplace safety in settings with exposure to radioactivity (29 CFR 1910.1096). Rules §245.850(d)1-E and §245.850(e) are incomplete and deficient, and these inadequacies can "constitute a serious threat"--indeed, deadly threat-- "to the public interest, safety, or welfare" of Illinois citizens." Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Notably absent from these proposed rules is a requirement for the testing of "produced water", the fluid that returns from the well during the later stage of production (after flowback). Under the proposed rules, "produced water" can be stored on site and/or can be "recycled", yet there is no testing requirement. Naturally occurring radioactive material (NORM) is found in "produced water" also. See Technologically enhanced naturally occurring radioactive materials in the oil industry (TENORM), Nukleonika 2009; 54(1):3-9, and sources cited therein, especially for TENORM in produced water in the U.S., available at [http://www.nukleonika.pl/www/back/full/vol54\\_2009/v54n1p003f.pdf](http://www.nukleonika.pl/www/back/full/vol54_2009/v54n1p003f.pdf). See also NORM is also found on scale in oil pipes and on fracking equipment. (See Kentucky Resources Council Proposes Comprehensive Plan For Investigating Radiological Contamination In Martha Oil Field. August 11, 2005. <http://www.kyrc.org/webnewspro/112381723236086.shtml>.) The health and safety of workers transporting produced water who will also be in the dark regarding the levels of radioactivity they will be exposed to. The risk of storing radioactive material in tanks not created for storing radioactive materials. The risk of "recycling" produced water—radioactivity cannot be removed by recycling. The risk to the public in transporting radioactive materials Argonne National Laboratory recently cautioned about radiological doses: "It is commonly accepted that efforts should be undertaken at all times to keep radiological doses 'as low as reasonably achievable,' which is referred to as the ALARA principle or requirement." Overview of Radiological Dose and Risk Assessment (April 2011). DNR is failing to even adequately test for radioactivity and therefore, will not know the levels of radioactivity. How, then, can

## Fair Economy Illinois

---

DNR adequately protect workers and the general public? Elaboration: IDNR does not define a Fixed Date ( $\pm X$  days) for testing. Day 1, <Hour 1 test results will be orders of magnitude lower than either Day 2 or Day 10 tests results, and Day 10 tests results will be significantly lower than Day 80 ( $\pm 7$  days) results. Failure to specify a Fixed Test Date ( $\pm X$  days) renders test data so many irrelevant apples and oranges and allows companies to report suppressed, meaningless results by reporting Day 1, < 1 Hour data. The figure below, provided by the USGS, illustrates the nature of the problem. Please note that radium is not tested at Day 1, < 1 Hour. However, radium coprecipitates with barium, which is represented in total dissolved solids (TDS). It will therefore track TDS fairly closely. Conclusion: companies will be testing the very first flowback water to emerge from a fracked well. It will be Day 1, Minute 1 test results. 2.) There are two pits on a frack pad, one for "emergency" flowback and another, smaller one for drill cuttings and drilling mud. It is a basic principle in horizontal fracking to steer the drill bit through the horizontal strata with the highest gamma radiation readings (GAPI logs). The reason is that radioactivity correlates highly with total organic content (TOC) in the rock, and TOC correlates highly with oil and gas yields. This means that rock cuttings in the smaller drill mud and cuttings frack pit will often be more radioactive than flowback water. The IDNR knows this; yet it does not call for testing of drill bit pits as allowed under the Powers and duties section of the Act (§1- 15). 3.) The term "adjacent to" requires a "precise, clear standard" [IAPA, §100/5-20]. None is given. Does "adjacent to" mean 6 inches, 16 inches, 6 feet, 16 feet, or 60 feet? The IDNR does not say. 4.) Frack pad pipes and equipment can become incredibly radioactive over time. The very large temperature and pressure drops, as fluids move to the surface from thousands of feet underground, means that aqueous radioactive salts precipitate out as scale on pipes and equipment. The levels of radioactivity in pipe scale can exceed 100,000 picoCuries per gram and constitute a hazard to workers, or others who are exposed to recycled scrap metal from gas and oil operations. Yet, IDNR does not call on its General Assembly deferred "Power and authority" [Act, §1-15(e)] to test pipe, tanks, sludge, and equipment. This issue has been an issue in the oil and gas industry since the 1980s. Consequences: According to studies by the Illinois State Geological Survey, the Illinois New Albany Shale Formation, the source rock for our oil and gas reserves, has above average levels of uranium (29 ppm). Uranium decays into radium and thence radon. Both uranium and radium are water soluble. As noted, the U.S. Geological Survey has found oil field brine or produced water in Southern Illinois to have Radium226 levels that average more than 1,000 picoCuries / liter (USGS 1999). That reading is 67 times above the maximum contamination level of the EPA. Radium226 has a half life of 1,600 years. Uranium228 has a half life of 4.468 billion years. If these water soluble salts leach into our aquifers, nearby communities will require--if possible--very expensive water treatment for the next 1,000 years. We may have to return to rainwater harvesting with the modern equivalent of cisterns. The radioactive levels for produced water from shale gas operations are likely to be 2 to 4 times higher than oilfield brine -- on average, 2,000 to 4,000 picoCuries per liter. In addition, radon levels in methane, propane, and ethane can be dangerously high. When it becomes commercial to extract shale gas from the SE corner of the state, major markets, such as Springfield and Chicago, will only be 0.9 and 1.4 days removed from shale gas wellheads. Even though radon222 has a half life of only 3.8 days, the closeness of major Illinois retail gas markets will mean that large number of people will be breathing in high levels of radon when they cook meals. The average level of indoor exposure to radon in Illinois is already 4.4

## Fair Economy Illinois

---

pCi/L ( American Lung Association 2013). The EPA maximum level--the point at which corrective action should be taken--is 4.0 pCi/L, and the preferred level is =3.0 pCi/L. The turn to shale gas, with its high levels of radon, will also turn a major Illinois public health problem in the wrong direction. Radioactive scale in pipe and equipment presents another problem; high levels of radioactivity have been found in school playground equipment and bleachers in school sports stadiums in Mississippi and Texas. Do we want untested oil and gas field scrap metal sold into Illinois markets? Do we want our children exposed on a daily basis to radioactive metal? The present rules creates no barriers to such an outcome. The problems cited above are why Illinois, with its large number of nuclear power plants, has a Low-Level Radioactive Waste Management Act. It and OSHA are the applicable State and Federal agencies with respect to the issue of radioactive waste and work safety standards in settings with exposure to radioactivity. If we faithfully follow applicable State and federal laws, Illinois can minimize the pernicious problems other states are going to face from the uncontrolled release of radioactive elements into their water and soil and work and non-work settings. We should prevent these problem from the start. Cleanup, after the oil and gas industry is gone, will be dreadfully expensive.. Recommendations: 1. Define the test date as = Day 21, the point at which increases in test results begin to level off. 2. Test for "radioactivity" in (1) flowback/produced water, (2) drill cuttings, soil "adjacent to" (3) storage tanks and (4) reserve pits, and (5) pipes and well pad equipment. 3. Define "adjacent to" as between 6 and 12 inches with test samples to be taken within the top 6 inches of soil 4. The rules should also require that the requirements of the Illinois Low Level Radioactivity Waste Management Act be followed.

Sincerely, Scott Condren Chicago, IL 60608

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Act §1-75(a)7 requires radioactivity testing "once per well site" for (1) flowback water and ground "adjacent to" (2) storage tanks and (3) reserve pits. Act § 1-120 requires IDNR compliance with all "applicable federal, State, and local laws." One applicable State law is the Illinois Low-Level Radioactive Waste Management Act (PA 83-991 / 420ILCS20). Another is the Occupational Health and Safety Administration (OSHA) standards for workplace safety in settings with exposure to radioactivity (29 CFR 1910.1096). Rules §245.850(d)1-E and §245.850(e) are incomplete and deficient, and these inadequacies can "constitute a serious threat"--indeed, deadly threat-- "to the public interest, safety, or welfare" of Illinois citizens." Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Notably absent from these proposed rules is a requirement for the testing of "produced water", the fluid that returns from the well during the later stage of production (after flowback). Under the proposed rules, "produced water" can be stored on site and/or can be "recycled", yet there is no testing requirement. Naturally occurring radioactive material (NORM) is found in "produced water" also. See Technologically enhanced naturally occurring radioactive materials in the oil industry (TENORM), Nukleonika 2009; 54(1):3-9, and sources cited therein, especially for TENORM in produced water in the U.S., available at [http://www.nukleonika.pl/www/back/full/vol54\\_2009/v54n1p003f.pdf](http://www.nukleonika.pl/www/back/full/vol54_2009/v54n1p003f.pdf). See also NORM is also found on scale in oil pipes and on fracking equipment. (See Kentucky Resources Council Proposes Comprehensive Plan For Investigating Radiological Contamination In Martha Oil Field. August 11, 2005. <http://www.kyrc.org/webnewspro/112381723236086.shtml>.) IDNR's definitions of "flowback water" and "produced water" are different. The two are distinguishably different enough that they are treated as separate types of fluid by both the Hydraulic Fracturing Regulatory Act and by the DNR Rules. Discharge of produced water onto the ground or into surface water or water drainage way is prohibited but it is not tested for radioactivity. This despite the fact that this fluid will be in contact with the naturally occurring radioactive elements in the ground for a longer period than the flowback and that it is much more likely to be radioactive. Problems: Failure to test produced water for radioactivity is problematic for a variety of reasons including: The health and safety of workers on the site who will be unaware of the levels of radioactivity they are being exposed to. The health and safety of workers transporting produced water who will also be in the dark regarding the levels of radioactivity they will be exposed to. The risk of storing radioactive material in tanks not created for storing radioactive materials. The risk of "recycling" produced water—radioactivity cannot be removed by recycling. The risk to the public in transporting radioactive materials Argonne National Laboratory recently cautioned about radiological doses: "It is commonly accepted that efforts should be undertaken at all times to keep radiological doses 'as low as reasonably achievable,' which is referred to as the ALARA principle or requirement." Overview of Radiological Dose and Risk Assessment (April 2011). DNR is failing to even adequately test for radioactivity and therefore, will not know the levels of radioactivity. How, then, can

## Fair Economy Illinois

---

DNR adequately protect workers and the general public? Elaboration: IDNR does not define a Fixed Date ( $\pm X$  days) for testing. Day 1, <Hour 1 test results will be orders of magnitude lower than either Day 2 or Day 10 tests results, and Day 10 tests results will be significantly lower than Day 80 ( $\pm 7$  days) results. Failure to specify a Fixed Test Date ( $\pm X$  days) renders test data so many irrelevant apples and oranges and allows companies to report suppressed, meaningless results by reporting Day 1, < 1 Hour data. The figure below, provided by the USGS, illustrates the nature of the problem. Please note that radium is not tested at Day 1, < 1 Hour. However, radium coprecipitates with barium, which is represented in total dissolved solids (TDS). It will therefore track TDS fairly closely. Conclusion: companies will be testing the very first flowback water to emerge from a fracked well. It will be Day 1, Minute 1 test results. 2.) DNR adequately protect workers and the general public? Elaboration: IDNR does not define a Fixed Date ( $\pm X$  days) for testing. Day 1, <Hour 1 test results will be orders of magnitude lower than either Day 2 or Day 10 tests results, and Day 10 tests results will be significantly lower than Day 80 ( $\pm 7$  days) results. Failure to specify a Fixed Test Date ( $\pm X$  days) renders test data so many irrelevant apples and oranges and allows companies to report suppressed, meaningless results by reporting Day 1, < 1 Hour data. The figure below, provided by the USGS, illustrates the nature of the problem. Please note that radium is not tested at Day 1, < 1 Hour. However, radium coprecipitates with barium, which is represented in total dissolved solids (TDS). It will therefore track TDS fairly closely. Conclusion: companies will be testing the very first flowback water to emerge from a fracked well. It will be Day 1, Minute 1 test results. 2.) There are two pits on a frack pad, one for "emergency" flowback and another, smaller one for drill cuttings and drilling mud. It is a basic principle in horizontal fracking to steer the drill bit through the horizontal strata with the highest gamma radiation readings (GAPI logs). The reason is that radioactivity correlates highly with total organic content (TOC) in the rock, and TOC correlates highly with oil and gas yields. This means that rock cuttings in the smaller drill mud and cuttings frack pit will often be more radioactive than flowback water. The IDNR knows this; yet it does not call for testing of drill bit pits as allowed under the Powers and duties section of the Act (§1- 15). 3.) The term "adjacent to" requires a "precise, clear standard" [IAPA, §100/5-20]. None is given. Does "adjacent to" mean 6 inches, 16 inches, 6 feet, 16 feet, or 60 feet? The IDNR does not say. 4.) Frack pad pipes and equipment can become incredibly radioactive over time. The very large temperature and pressure drops, as fluids move to the surface from thousands of feet underground, means that aqueous radioactive salts precipitate out as scale on pipes and equipment. The levels of radioactivity in pipe scale can exceed 100,000 picoCuries per gram and constitute a hazard to workers, or others who are exposed to recycled scrap metal from gas and oil operations. Yet, IDNR does not call on its General Assembly deferred "Power and authority" [Act, §1-15(e)] to test pipe, tanks, sludge, and equipment. This issue has been an issue in the oil and gas industry since the 1980s. Consequences: According to studies by the Illinois State Geological Survey, the Illinois New Albany Shale Formation, the source rock for our oil and gas reserves, has above average levels of uranium (29 ppm). Uranium decays into radium and thence radon. Both uranium and radium are water soluble. As noted, the U.S. Geological Survey has found oil field brine or produced water in Southern Illinois to have Radium226 levels that average more than 1,000 picoCuries / liter (USGS 1999). That reading is 67 times above the maximum contamination level of the EPA. Radium226 has a half life of 1,600 years. Uranium228 has a half life of 4.468 billion years. If these water soluble salts leach into our aquifers, nearby communities will require--if possible--very expensive water treatment for the next 1,000 years. We may have to return to rainwater harvesting with the modern equivalent of cisterns. The radioactive levels for produced water from shale gas operations are likely to be 2 to 4 times higher than oilfield brine -- on average, 2,000 to 4,000 picoCuries per liter. In addition, radon levels in methane, propane, and ethane can be dangerously high. When it becomes commercial to extract shale gas from the SE corner of the state, major markets, such as Springfield and Chicago, will only be 0.9 and 1.4 days removed from shale gas wellheads. Even though radon222 has a half life of only 3.8 days, the closeness of major Illinois retail gas markets will mean that large number of people will be breathing in high levels of radon when they cook meals. The average level of indoor exposure to radon in Illinois is already 4.4

## Fair Economy Illinois

---

pCi/L ( American Lung Association 2013). The EPA maximum level--the point at which corrective action should be taken--is 4.0 pCi/L, and the preferred level is =3.0 pCi/L. The turn to shale gas, with its high levels of radon, will also turn a major Illinois public health problem in the wrong direction. Radioactive scale in pipe and equipment presents another problem; high levels of radioactivity have been found in school playground equipment and bleachers in school sports stadiums in Mississippi and Texas. Do we want untested oil and gas field scrap metal sold into Illinois markets? Do we want our children exposed on a daily basis to radioactive metal? The present rules creates no barriers to such an outcome. The problems cited above are why Illinois, with its large number of nuclear power plants, has a Low-Level Radioactive Waste Management Act. It and OSHA are the applicable State and Federal agencies with respect to the issue of radioactive waste and work safety standards in settings with exposure to radioactivity. If we faithfully follow applicable State and federal laws, Illinois can minimize the pernicious problems other states are going to face from the uncontrolled release of radioactive elements into their water and soil and work and non-work settings. We should prevent these problem from the start. Cleanup, after the oil and gas industry is gone, will be dreadfully expensive.. Recommendations: 1. Define the test date as = Day 21, the point at which increases in test results begin to level off. 2. Test for "radioactivity" in (1) flowback/produced water, (2) drill cuttings, soil "adjacent to" (3) storage tanks and (4) reserve pits, and (5) pipes and well pad equipment. 3. Define "adjacent to" as between 6 and 12 inches with test samples to be taken within the top 6 inches of soil 4. The rules should also require that the requirements of the Illinois Low Level Radioactivity Waste Management Act be followed.

Sincerely, Shaden Amara Naperville, IL 60564

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Act §1-75(a)7 requires radioactivity testing "once per well site" for (1) flowback water and ground "adjacent to" (2) storage tanks and (3) reserve pits. Act § 1-120 requires IDNR compliance with all "applicable federal, State, and local laws." One applicable State law is the Illinois Low-Level Radioactive Waste Management Act (PA 83-991 / 420ILCS20). Another is the Occupational Health and Safety Administration (OSHA) standards for workplace safety in settings with exposure to radioactivity (29 CFR 1910.1096). Rules §245.850(d)1-E and §245.850(e) are incomplete and deficient, and these inadequacies can "constitute a serious threat"--indeed, deadly threat-- "to the public interest, safety, or welfare" of Illinois citizens." Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Notably absent from these proposed rules is a requirement for the testing of "produced water", the fluid that returns from the well during the later stage of production (after flowback). Under the proposed rules, "produced water" can be stored on site and/or can be "recycled", yet there is no testing requirement. Naturally occurring radioactive material (NORM) is found in "produced water" also. See Technologically enhanced naturally occurring radioactive materials in the oil industry (TENORM), Nukleonika 2009; 54(1):3-9, and sources cited therein, especially for TENORM in produced water in the U.S., available at [http://www.nukleonika.pl/www/back/full/vol54\\_2009/v54n1p003f.pdf](http://www.nukleonika.pl/www/back/full/vol54_2009/v54n1p003f.pdf). See also NORM is also found on scale in oil pipes and on fracking equipment. (See Kentucky Resources Council Proposes Comprehensive Plan For Investigating Radiological Contamination In Martha Oil Field. August 11, 2005. <http://www.kyrc.org/webnewspro/112381723236086.shtml>.) IDNR's definitions of "flowback water" and "produced water" are different. The two are distinguishably different enough that they are treated as separate types of fluid by both the Hydraulic Fracturing Regulatory Act and by the DNR Rules. Discharge of produced water onto the ground or into surface water or water drainage way is prohibited but it is not tested for radioactivity. This despite the fact that this fluid will be in contact with the naturally occurring radioactive elements in the ground for a longer period than the flowback and that it is much more likely to be radioactive. Problems: Failure to test produced water for radioactivity is problematic for a variety of reasons including: The health and safety of workers on the site who will be unaware of the levels of radioactivity they are being exposed to. The health and safety of workers transporting produced water who will also be in the dark regarding the levels of radioactivity they will be exposed to. The risk of storing radioactive material in tanks not created for storing radioactive materials. The risk of "recycling" produced water—radioactivity cannot be removed by recycling. The risk to the public in transporting radioactive materials Argonne National Laboratory recently cautioned about radiological doses: "It is commonly accepted that efforts should be undertaken at all times to keep radiological doses 'as low as reasonably achievable,' which is referred to as the ALARA principle or requirement." Overview of Radiological Dose and Risk Assessment (April 2011). DNR is failing to even adequately test for radioactivity and therefore, will not know the levels of radioactivity. How, then, can

## Fair Economy Illinois

---

DNR adequately protect workers and the general public? Elaboration: IDNR does not define a Fixed Date ( $\pm X$  days) for testing. Day 1, <Hour 1 test results will be orders of magnitude lower than either Day 2 or Day 10 tests results, and Day 10 tests results will be significantly lower than Day 80 ( $\pm 7$  days) results. Failure to specify a Fixed Test Date ( $\pm X$  days) renders test data so many irrelevant apples and oranges and allows companies to report suppressed, meaningless results by reporting Day 1, < 1 Hour data. The figure below, provided by the USGS, illustrates the nature of the problem. Please note that radium is not tested at Day 1, < 1 Hour. However, radium coprecipitates with barium, which is represented in total dissolved solids (TDS). It will therefore track TDS fairly closely. Conclusion: companies will be testing the very first flowback water to emerge from a fracked well. It will be Day 1, Minute 1 test results. 2.) There are two pits on a frack pad, one for "emergency" flowback and another, smaller one for drill cuttings and drilling mud. It is a basic principle in horizontal fracking to steer the drill bit through the horizontal strata with the highest gamma radiation readings (GAPI logs). The reason is that radioactivity correlates highly with total organic content (TOC) in the rock, and TOC correlates highly with oil and gas yields. This means that rock cuttings in the smaller drill mud and cuttings frack pit will often be more radioactive than flowback water. The IDNR knows this; yet it does not call for testing of drill bit pits as allowed under the Powers and duties section of the Act (§1- 15). 3.) The term "adjacent to" requires a "precise, clear standard" [IAPA, §100/5-20]. None is given. Does "adjacent to" mean 6 inches, 16 inches, 6 feet, 16 feet, or 60 feet? The IDNR does not say. 4.) Frack pad pipes and equipment can become incredibly radioactive over time. The very large temperature and pressure drops, as fluids move to the surface from thousands of feet underground, means that aqueous radioactive salts precipitate out as scale on pipes and equipment. The levels of radioactivity in pipe scale can exceed 100,000 picoCuries per gram and constitute a hazard to workers, or others who are exposed to recycled scrap metal from gas and oil operations. Yet, IDNR does not call on its General Assembly deferred "Power and authority" [Act, §1-15(e)] to test pipe, tanks, sludge, and equipment. This issue has been an issue in the oil and gas industry since the 1980s. Consequences: According to studies by the Illinois State Geological Survey, the Illinois New Albany Shale Formation, the source rock for our oil and gas reserves, has above average levels of uranium (29 ppm). Uranium decays into radium and thence radon. Both uranium and radium are water soluble. As noted, the U.S. Geological Survey has found oil field brine or produced water in Southern Illinois to have Radium226 levels that average more than 1,000 picoCuries / liter (USGS 1999). That reading is 67 times above the maximum contamination level of the EPA. Radium226 has a half life of 1,600 years. Uranium228 has a half life of 4.468 billion years. If these water soluble salts leach into our aquifers, nearby communities will require--if possible--very expensive water treatment for the next 1,000 years. We may have to return to rainwater harvesting with the modern equivalent of cisterns. The radioactive levels for produced water from shale gas operations are likely to be 2 to 4 times higher than oilfield brine -- on average, 2,000 to 4,000 picoCuries per liter. In addition, radon levels in methane, propane, and ethane can be dangerously high. In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Act §1-75(a)7 requires radioactivity testing "once per well site" for (1) flowback water and ground "adjacent to" (2) storage tanks and (3) reserve pits. Act § 1-120 requires IDNR compliance with all "applicable federal, State, and local laws." One applicable State law is the Illinois Low-Level Radioactive Waste Management Act (PA 83-991 / 420ILCS20). Another is the Occupational Health and Safety Administration (OSHA) standards for workplace safety in settings with exposure to radioactivity (29 CFR 1910.1096). Rules §245.850(d)1-E and §245.850(e) are incomplete and deficient, and these inadequacies can "constitute a serious threat"--indeed, deadly threat-- "to the public interest, safety, or welfare" of Illinois citizens." Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Notably absent from these proposed rules is a requirement for the testing of "produced water", the fluid that returns from the well during the later stage of production (after flowback). Under the proposed rules, "produced water" can be stored on site and/or can be "recycled", yet there is no testing requirement. Naturally occurring radioactive material (NORM) is found in "produced water" also. See Technologically enhanced naturally occurring radioactive materials in the oil industry (TENORM), Nukleonika 2009; 54(1):3-9, and sources cited therein, especially for TENORM in produced water in the U.S., available at [http://www.nukleonika.pl/www/back/full/vol54\\_2009/v54n1p003f.pdf](http://www.nukleonika.pl/www/back/full/vol54_2009/v54n1p003f.pdf). See also NORM is also found on scale in oil pipes and on fracking equipment. (See Kentucky Resources Council Proposes Comprehensive Plan For Investigating Radiological Contamination In Martha Oil Field. August 11, 2005. <http://www.kyrc.org/webnewspro/112381723236086.shtml>.) IDNR's definitions of "flowback water" and "produced water" are different. The two are distinguishably different enough that they are treated as separate types of fluid by both the Hydraulic Fracturing Regulatory Act and by the DNR Rules. Discharge of produced water onto the ground or into surface water or water drainage way is prohibited but it is not tested for radioactivity. This despite the fact that this fluid will be in contact with the naturally occurring radioactive elements in the ground for a longer period than the flowback and that it is much more likely to be radioactive. Problems: Failure to test produced water for radioactivity is problematic for a variety of reasons including: The health and safety of workers on the site who will be unaware of the levels of radioactivity they are being exposed to. The health and safety of workers transporting produced water who will also be in the dark regarding the levels of radioactivity they will be exposed to. The risk of storing radioactive material in tanks not created for storing radioactive materials. The risk of "recycling" produced water—radioactivity cannot be removed by recycling. The risk to the public in transporting radioactive materials Argonne National Laboratory recently cautioned about radiological doses: "It is commonly accepted that efforts should be undertaken at all times to keep radiological doses 'as low as reasonably achievable,' which is referred to as the ALARA principle or requirement." Overview of Radiological Dose and Risk Assessment (April 2011). DNR is failing to even adequately test for radioactivity and therefore, will not know the levels of radioactivity. How, then, can

## Fair Economy Illinois

---

DNR adequately protect workers and the general public? Elaboration: IDNR does not define a Fixed Date ( $\pm X$  days) for testing. Day 1, <Hour 1 test results will be orders of magnitude lower than either Day 2 or Day 10 tests results, and Day 10 tests results will be significantly lower than Day 80 ( $\pm 7$  days) results. Failure to specify a Fixed Test Date ( $\pm X$  days) renders test data so many irrelevant apples and oranges and allows companies to report suppressed, meaningless results by reporting Day 1, < 1 Hour data. The figure below, provided by the USGS, illustrates the nature of the problem. Please note that radium is not tested at Day 1, < 1 Hour. However, radium coprecipitates with barium, which is represented in total dissolved solids (TDS). It will therefore track TDS fairly closely. Conclusion: companies will be testing the very first flowback water to emerge from a fracked well. It will be Day 1, Minute 1 test results. 2.) There are two pits on a frack pad, one for "emergency" flowback and another, smaller one for drill cuttings and drilling mud. It is a basic principle in horizontal fracking to steer the drill bit through the horizontal strata with the highest gamma radiation readings (GAPI logs). The reason is that radioactivity correlates highly with total organic content (TOC) in the rock, and TOC correlates highly with oil and gas yields. This means that rock cuttings in the smaller drill mud and cuttings frack pit will often be more radioactive than flowback water. The IDNR knows this; yet it does not call for testing of drill bit pits as allowed under the Powers and duties section of the Act (§1- 15). 3.) The term "adjacent to" requires a "precise, clear standard" [IAPA, §100/5-20]. None is given. Does "adjacent to" mean 6 inches, 16 inches, 6 feet, 16 feet, or 60 feet? The IDNR does not say. 4.) Frack pad pipes and equipment can become incredibly radioactive over time. The very large temperature and pressure drops, as fluids move to the surface from thousands of feet underground, means that aqueous radioactive salts precipitate out as scale on pipes and equipment. The levels of radioactivity in pipe scale can exceed 100,000 picoCuries per gram and constitute a hazard to workers, or others who are exposed to recycled scrap metal from gas and oil operations. Yet, IDNR does not call on its General Assembly deferred "Power and authority" [Act, §1-15(e)] to test pipe, tanks, sludge, and equipment. This issue has been an issue in the oil and gas industry since the 1980s. Consequences: According to studies by the Illinois State Geological Survey, the Illinois New Albany Shale Formation, the source rock for our oil and gas reserves, has above average levels of uranium (29 ppm). Uranium decays into radium and thence radon. Both uranium and radium are water soluble. As noted, the U.S. Geological Survey has found oil field brine or produced water in Southern Illinois to have Radium226 levels that average more than 1,000 picoCuries / liter (USGS 1999). That reading is 67 times above the maximum contamination level of the EPA. Radium226 has a half life of 1,600 years. Uranium228 has a half life of 4.468 billion years. If these water soluble salts leach into our aquifers, nearby communities will require--if possible--very expensive water treatment for the next 1,000 years. We may have to return to rainwater harvesting with the modern equivalent of cisterns. The radioactive levels for produced water from shale gas operations are likely to be 2 to 4 times higher than oilfield brine -- on average, 2,000 to 4,000 picoCuries per liter. In addition, radon levels in methane, propane, and ethane can be dangerously high. When it becomes commercial to extract shale gas from the SE corner of the state, major markets, such as Springfield and Chicago, will only be 0.9 and 1.4 days removed from shale gas wellheads. Even though radon222 has a half life of only 3.8 days, the closeness of major Illinois retail gas markets will mean that large number of people will be breathing in high levels of radon when they cook meals. The average level of indoor exposure to radon in Illinois is already 4.4

## Fair Economy Illinois

---

pCi/L ( American Lung Association 2013). The EPA maximum level--the point at which corrective action should be taken--is 4.0 pCi/L, and the preferred level is =3.0 pCi/L. The turn to shale gas, with its high levels of radon, will also turn a major Illinois public health problem in the wrong direction. Radioactive scale in pipe and equipment presents another problem; high levels of radioactivity have been found in school playground equipment and bleachers in school sports stadiums in Mississippi and Texas. Do we want untested oil and gas field scrap metal sold into Illinois markets? Do we want our children exposed on a daily basis to radioactive metal? The present rules creates no barriers to such an outcome. The problems cited above are why Illinois, with its large number of nuclear power plants, has a Low-Level Radioactive Waste Management Act. It and OSHA are the applicable State and Federal agencies with respect to the issue of radioactive waste and work safety standards in settings with exposure to radioactivity. If we faithfully follow applicable State and federal laws, Illinois can minimize the pernicious problems other states are going to face from the uncontrolled release of radioactive elements into their water and soil and work and non-work settings. We should prevent these problem from the start. Cleanup, after the oil and gas industry is gone, will be dreadfully expensive.. Recommendations: 1. Define the test date as = Day 21, the point at which increases in test results begin to level off. 2. Test for "radioactivity" in (1) flowback/produced water, (2) drill cuttings, soil "adjacent to" (3) storage tanks and (4) reserve pits, and (5) pipes and well pad equipment. 3. Define "adjacent to" as between 6 and 12 inches with test samples to be taken within the top 6 inches of soil 4. The rules should also require that the requirements of the Illinois Low Level Radioactivity Waste Management Act be followed.

Sincerely, Shreya Kalva Chicago, IL 60637

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Act §1-75(a)7 requires radioactivity testing "once per well site" for (1) flowback water and ground "adjacent to" (2) storage tanks and (3) reserve pits. Act § 1-120 requires IDNR compliance with all "applicable federal, State, and local laws." One applicable State law is the Illinois Low-Level Radioactive Waste Management Act (PA 83-991 / 420ILCS20). Another is the Occupational Health and Safety Administration (OSHA) standards for workplace safety in settings with exposure to radioactivity (29 CFR 1910.1096). Rules §245.850(d)1-E and §245.850(e) are incomplete and deficient, and these inadequacies can "constitute a serious threat"--indeed, deadly threat-- "to the public interest, safety, or welfare" of Illinois citizens." Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Notably absent from these proposed rules is a requirement for the testing of "produced water", the fluid that returns from the well during the later stage of production (after flowback). Under the proposed rules, "produced water" can be stored on site and/or can be "recycled", yet there is no testing requirement. Naturally occurring radioactive material (NORM) is found in "produced water" also. See Technologically enhanced naturally occurring radioactive materials in the oil industry (TENORM), Nukleonika 2009; 54(1):3-9, and sources cited therein, especially for TENORM in produced water in the U.S., available at [http://www.nukleonika.pl/www/back/full/vol54\\_2009/v54n1p003f.pdf](http://www.nukleonika.pl/www/back/full/vol54_2009/v54n1p003f.pdf). See also NORM is also found on scale in oil pipes and on fracking equipment. (See Kentucky Resources Council Proposes Comprehensive Plan For Investigating Radiological Contamination In Martha Oil Field. August 11, 2005. <http://www.kyrc.org/webnewspro/112381723236086.shtml>.) IDNR's definitions of "flowback water" and "produced water" are different. The two are distinguishably different enough that they are treated as separate types of fluid by both the Hydraulic Fracturing Regulatory Act and by the DNR Rules. Discharge of produced water onto the ground or into surface water or water drainage way is prohibited but it is not tested for radioactivity. This despite the fact that this fluid will be in contact with the naturally occurring radioactive elements in the ground for a longer period than the flowback and that it is much more likely to be radioactive. Problems: Failure to test produced water for radioactivity is problematic for a variety of reasons including: The health and safety of workers on the site who will be unaware of the levels of radioactivity they are being exposed to. The health and safety of workers transporting produced water who will also be in the dark regarding the levels of radioactivity they will be exposed to. The risk of storing radioactive material in tanks not created for storing radioactive materials. The risk of "recycling" produced water—radioactivity cannot be removed by recycling. The risk to the public in transporting radioactive materials Argonne National Laboratory recently cautioned about radiological doses: "It is commonly accepted that efforts should be undertaken at all times to keep radiological doses 'as low as reasonably achievable,' which is referred to as the ALARA principle or requirement." Overview of Radiological Dose and Risk Assessment (April 2011). DNR is failing to even adequately test for radioactivity and therefore, will not know the levels of radioactivity. How, then, can

DNR adequately protect workers and the general public? Elaboration: IDNR does not define a Fixed Date ( $\pm X$  days) for testing. Day 1, <Hour 1 test results will be orders of magnitude lower than either Day 2 or Day 10 tests results, and Day 10 tests results will be significantly lower than Day 80 ( $\pm 7$  days) results. Failure to specify a Fixed Test Date ( $\pm X$  days) renders test data so many irrelevant apples and oranges and allows companies to report suppressed, meaningless results by reporting Day 1, < 1 Hour data. The figure below, provided by the USGS, illustrates the nature of the problem. Please note that radium is not tested at Day 1, < 1 Hour. However, radium coprecipitates with barium, which is represented in total dissolved solids (TDS). It will therefore track TDS fairly closely. Conclusion: companies will be testing the very first flowback water to emerge from a fracked well. It will be Day 1, Minute 1 test results. 2.) There are two pits on a frack pad, one for "emergency" flowback and another, smaller one for drill cuttings and drilling mud. It is a basic principle in horizontal fracking to steer the drill bit through the horizontal strata with the highest gamma radiation readings (GAPI logs). The reason is that radioactivity correlates highly with total organic content (TOC) in the rock, and TOC correlates highly with oil and gas yields. This means that rock cuttings in the smaller drill mud and cuttings frack pit will often be more radioactive than flowback water. The IDNR knows this; yet it does not call for testing of drill bit pits as allowed under the Powers and duties section of the Act (§1- 15). 3.) The term "adjacent to" requires a "precise, clear standard" [IAPA, §100/5-20]. None is given. Does "adjacent to" mean 6 inches, 16 inches, 6 feet, 16 feet, or 60 feet? The IDNR does not say. 4.) Frack pad pipes and equipment can become incredibly radioactive over time. The very large temperature and pressure drops, as fluids move to the surface from thousands of feet underground, means that aqueous radioactive salts precipitate out as scale on pipes and equipment. The levels of radioactivity in pipe scale can exceed 100,000 picoCuries per gram and constitute a hazard to workers, or others who are exposed to recycled scrap metal from gas and oil operations. Yet, IDNR does not call on its General Assembly deferred "Power and authority" [Act, §1-15(e)] to test pipe, tanks, sludge, and equipment. This issue has been an issue in the oil and gas industry since the 1980s. Consequences: According to studies by the Illinois State Geological Survey, the Illinois New Albany Shale Formation, the source rock for our oil and gas reserves, has above average levels of uranium (29 ppm). Uranium decays into radium and thence radon. Both uranium and radium are water soluble. As noted, the U.S. Geological Survey has found oil field brine or produced water in Southern Illinois to have Radium226 levels that average more than 1,000 picoCuries / liter (USGS 1999). That reading is 67 times above the maximum contamination level of the EPA. Radium226 has a half life of 1,600 years. Uranium228 has a half life of 4.468 billion years. If these water soluble salts leach into our aquifers, nearby communities will require--if possible--very expensive water treatment for the next 1,000 years. We may have to return to rainwater harvesting with the modern equivalent of cisterns. The radioactive levels for produced water from shale gas operations are likely to be 2 to 4 times higher than oilfield brine -- on average, 2,000 to 4,000 picoCuries per liter. In addition, radon levels in methane, propane, and ethane can be dangerously high. When it becomes commercial to extract shale gas from the SE corner of the state, major markets, such as Springfield and Chicago, will only be 0.9 and 1.4 days removed from shale gas wellheads. Even though radon222 has a half life of only 3.8 days, the closeness of major Illinois retail gas markets will mean that large number of people will be breathing in high levels of radon when they cook meals. The average level of indoor exposure to radon in Illinois is already 4.4

## Fair Economy Illinois

---

pCi/L ( American Lung Association 2013). The EPA maximum level--the point at which corrective action should be taken--is 4.0 pCi/L, and the preferred level is =3.0 pCi/L. The turn to shale gas, with its high levels of radon, will also turn a major Illinois public health problem in the wrong direction. Radioactive scale in pipe and equipment presents another problem; high levels of radioactivity have been found in school playground equipment and bleachers in school sports stadiums in Mississippi and Texas. Do we want untested oil and gas field scrap metal sold into Illinois markets? Do we want our children exposed on a daily basis to radioactive metal? The present rules creates no barriers to such an outcome. The problems cited above are why Illinois, with its large number of nuclear power plants, has a Low-Level Radioactive Waste Management Act. It and OSHA are the applicable State and Federal agencies with respect to the issue of radioactive waste and work safety standards in settings with exposure to radioactivity. If we faithfully follow applicable State and federal laws, Illinois can minimize the pernicious problems other states are going to face from the uncontrolled release of radioactive elements into their water and soil and work and non-work settings. We should prevent these problem from the start. Cleanup, after the oil and gas industry is gone, will be dreadfully expensive.. Recommendations: 1. Define the test date as = Day 21, the point at which increases in test results begin to level off. 2. Test for "radioactivity" in (1) flowback/produced water, (2) drill cuttings, soil "adjacent to" (3) storage tanks and (4) reserve pits, and (5) pipes and well pad equipment. 3. Define "adjacent to" as between 6 and 12 inches with test samples to be taken within the top 6 inches of soil 4. The rules should also require that the requirements of the Illinois Low Level Radioactivity Waste Management Act be followed.

Sincerely, Shreya Kathuria Vernon Hills, IL 60061

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Act §1-75(a)7 requires radioactivity testing "once per well site" for (1) flowback water and ground "adjacent to" (2) storage tanks and (3) reserve pits. Act § 1-120 requires IDNR compliance with all "applicable federal, State, and local laws." One applicable State law is the Illinois Low-Level Radioactive Waste Management Act (PA 83-991 / 420ILCS20). Another is the Occupational Health and Safety Administration (OSHA) standards for workplace safety in settings with exposure to radioactivity (29 CFR 1910.1096). Rules §245.850(d)1-E and §245.850(e) are incomplete and deficient, and these inadequacies can "constitute a serious threat"--indeed, deadly threat-- "to the public interest, safety, or welfare" of Illinois citizens." Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Notably absent from these proposed rules is a requirement for the testing of "produced water", the fluid that returns from the well during the later stage of production (after flowback). Under the proposed rules, "produced water" can be stored on site and/or can be "recycled", yet there is no testing requirement. Naturally occurring radioactive material (NORM) is found in "produced water" also. See Technologically enhanced naturally occurring radioactive materials in the oil industry (TENORM), Nukleonika 2009; 54(1):3-9, and sources cited therein, especially for TENORM in produced water in the U.S., available at [http://www.nukleonika.pl/www/back/full/vol54\\_2009/v54n1p003f.pdf](http://www.nukleonika.pl/www/back/full/vol54_2009/v54n1p003f.pdf). See also NORM is also found on scale in oil pipes and on fracking equipment. (See Kentucky Resources Council Proposes Comprehensive Plan For Investigating Radiological Contamination In Martha Oil Field. August 11, 2005. <http://www.kyrc.org/webnewspro/112381723236086.shtml>.) IDNR's definitions of "flowback water" and "produced water" are different. The two are distinguishably different enough that they are treated as separate types of fluid by both the Hydraulic Fracturing Regulatory Act and by the DNR Rules. Discharge of produced water onto the ground or into surface water or water drainage way is prohibited but it is not tested for radioactivity. This despite the fact that this fluid will be in contact with the naturally occurring radioactive elements in the ground for a longer period than the flowback and that it is much more likely to be radioactive. Problems: Failure to test produced water for radioactivity is problematic for a variety of reasons including: The health and safety of workers on the site who will be unaware of the levels of radioactivity they are being exposed to. The health and safety of workers transporting produced water who will also be in the dark regarding the levels of radioactivity they will be exposed to. The risk of storing radioactive material in tanks not created for storing radioactive materials. The risk of "recycling" produced water—radioactivity cannot be removed by recycling. The risk to the public in transporting radioactive materials Argonne National Laboratory recently cautioned about radiological doses: "It is commonly accepted that efforts should be undertaken at all times to keep radiological doses 'as low as reasonably achievable,' which is referred to as the ALARA principle or requirement." DNR adequately protect workers and the general public? Elaboration: IDNR does not define a Fixed Date ( $\pm X$  days) for testing. Day 1, <Hour 1 test results will be orders of magnitude lower than either Day 2 or Day 10 tests results, and Day 10 tests results will be significantly lower than Day 80 ( $\pm 7$  days) results. Failure to specify a Fixed Test Date ( $\pm X$  days) renders test data so many irrelevant apples and oranges and allows companies to report suppressed, meaningless results by reporting Day 1, < 1 Hour data. The figure below, provided by the USGS, illustrates the nature of the problem. Please note that radium is not tested at Day 1, < 1 Hour. However, radium coprecipitates with barium, which is represented in total dissolved solids (TDS). It will therefore track TDS fairly closely. Conclusion: companies will be testing the very first flowback water to emerge from a fracked well. It will be Day 1, Minute 1 test results. 2.) There are two pits on a frack pad, one for "emergency" flowback and another, smaller one for drill cuttings and drilling mud. It is a basic principle in horizontal fracking to steer the drill bit through the horizontal strata with the highest gamma radiation readings (GAPI logs). The reason is that radioactivity correlates highly with total organic content (TOC) in the rock, and TOC correlates highly with oil and gas yields. This means that rock cuttings in the smaller drill mud and cuttings frack pit will often be more radioactive than flowback water. The IDNR knows this; yet it does not call for testing of drill bit pits as allowed under the Powers and duties section of the Act (§1- 15). 3.) The term "adjacent to" requires a "precise, clear standard" [IAPA, §100/5-20]. None is given. Does "adjacent to" mean 6 inches, 16 inches, 6 feet, 16 feet, or 60 feet? The IDNR does not say. 4.) Frack pad pipes and equipment can become incredibly radioactive over time. The very large temperature and pressure drops, as fluids move to the surface from thousands of feet underground, means that aqueous radioactive salts precipitate out as scale on pipes and equipment. The levels of radioactivity in pipe scale can exceed 100,000 picoCuries per gram and constitute a hazard to workers, or others who are exposed to recycled scrap metal from gas and oil operations. Yet, IDNR does not call on its General Assembly deferred "Power and authority" [Act, §1-15(e)] to test pipe, tanks, sludge, and equipment. This issue has been an issue in the oil and gas industry since the 1980s. Consequences: According to studies by the Illinois State Geological Survey, the Illinois New Albany Shale Formation, the source rock for our oil and gas reserves, has above average levels of uranium (29 ppm). Uranium decays into radium and thence radon. Both uranium and radium are water soluble. As noted, the U.S. Geological Survey has found oil field brine or produced water in Southern Illinois to have Radium226 levels that average more than 1,000 picoCuries / liter (USGS 1999). That reading is 67 times above the maximum contamination level of the EPA. Radium226 has a half life of 1,600 years. Uranium228 has a half life of 4.468 billion years. If these water soluble salts leach into our aquifers, nearby communities will require--if possible--very expensive water treatment for the next 1,000 years. We may have to return to rainwater harvesting with the modern equivalent of cisterns. The radioactive levels for produced water from shale gas operations are likely to be 2 to 4 times higher than oilfield brine -- on average, 2,000 to 4,000 picoCuries per liter. In addition, radon levels in methane, propane, and ethane can be dangerously high. When it becomes commercial to extract shale gas from the SE corner of the state, major markets, such as Springfield and Chicago, will only be 0.9 and 1.4 days removed from shale gas wellheads. Even though radon222 has a half life of only 3.8 days, the closeness of major Illinois retail gas markets will mean that large number of people will be breathing in high levels of radon when they cook meals. The average level of indoor exposure to radon in Illinois is already 4.4

## Fair Economy Illinois

---

pCi/L ( American Lung Association 2013). The EPA maximum level--the point at which corrective action should be taken--is 4.0 pCi/L, and the preferred level is =3.0 pCi/L. The turn to shale gas, with its high levels of radon, will also turn a major Illinois public health problem in the wrong direction. Radioactive scale in pipe and equipment presents another problem; high levels of radioactivity have been found in school playground equipment and bleachers in school sports stadiums in Mississippi and Texas. Do we want untested oil and gas field scrap metal sold into Illinois markets? Do we want our children exposed on a daily basis to radioactive metal? The present rules creates no barriers to such an outcome. The problems cited above are why Illinois, with its large number of nuclear power plants, has a Low-Level Radioactive Waste Management Act. It and OSHA are the applicable State and Federal agencies with respect to the issue of radioactive waste and work safety standards in settings with exposure to radioactivity. If we faithfully follow applicable State and federal laws, Illinois can minimize the pernicious problems other states are going to face from the uncontrolled release of radioactive elements into their water and soil and work and non-work settings. We should prevent these problem from the start. Cleanup, after the oil and gas industry is gone, will be dreadfully expensive.. Recommendations: 1. Define the test date as = Day 21, the point at which increases in test results begin to level off. 2. Test for "radioactivity" in (1) flowback/produced water, (2) drill cuttings, soil "adjacent to" (3) storage tanks and (4) reserve pits, and (5) pipes and well pad equipment. 3. Define "adjacent to" as between 6 and 12 inches with test samples to be taken within the top 6 inches of soil 4. The rules should also require that the requirements of the Illinois Low Level Radioactivity Waste Management Act be followed.

Sincerely, Ta Promlee Chicago, IL 60645

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Act §1-75(a)7 requires radioactivity testing "once per well site" for (1) flowback water and ground "adjacent to" (2) storage tanks and (3) reserve pits. Act § 1-120 requires IDNR compliance with all "applicable federal, State, and local laws." One applicable State law is the Illinois Low-Level Radioactive Waste Management Act (PA 83-991 / 420ILCS20). Another is the Occupational Health and Safety Administration (OSHA) standards for workplace safety in settings with exposure to radioactivity (29 CFR 1910.1096). Rules §245.850(d)1-E and §245.850(e) are incomplete and deficient, and these inadequacies can "constitute a serious threat"--indeed, deadly threat-- "to the public interest, safety, or welfare" of Illinois citizens." Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Notably absent from these proposed rules is a requirement for the testing of "produced water", the fluid that returns from the well during the later stage of production (after flowback). Under the proposed rules, "produced water" can be stored on site and/or can be "recycled", yet there is no testing requirement. Naturally occurring radioactive material (NORM) is found in "produced water" also. See Technologically enhanced naturally occurring radioactive materials in the oil industry (TENORM), Nukleonika 2009; 54(1):3-9, and sources cited therein, especially for TENORM in produced water in the U.S., available at [http://www.nukleonika.pl/www/back/full/vol54\\_2009/v54n1p003f.pdf](http://www.nukleonika.pl/www/back/full/vol54_2009/v54n1p003f.pdf). See also NORM is also found on scale in oil pipes and on fracking equipment. (See Kentucky Resources Council Proposes Comprehensive Plan For Investigating Radiological Contamination In Martha Oil Field. August 11, 2005. <http://www.kyrc.org/webnewspro/112381723236086.shtml>.) IDNR's definitions of "flowback water" and "produced water" are different. The two are distinguishably different enough that they are treated as separate types of fluid by both the Hydraulic Fracturing Regulatory Act and by the DNR Rules. Discharge of produced water onto the ground or into surface water or water drainage way is prohibited but it is not tested for radioactivity. This despite the fact that this fluid will be in contact with the naturally occurring radioactive elements in the ground for a longer period than the flowback and that it is much more likely to be radioactive. Problems: Failure to test produced water for radioactivity is problematic for a variety of reasons including: The health and safety of workers on the site who will be unaware of the levels of radioactivity they are being exposed to. The health and safety of workers transporting produced water who will also be in the dark regarding the levels of radioactivity they will be exposed to. The risk of storing radioactive material in tanks not created for storing radioactive materials. The risk of "recycling" produced water—radioactivity cannot be removed by recycling. The risk to the public in transporting radioactive materials Argonne National Laboratory recently cautioned about radiological doses: "It is commonly accepted that efforts should be undertaken at all times to keep radiological doses 'as low as reasonably achievable,' which is referred to as the ALARA principle or requirement." Overview of Radiological Dose and Risk Assessment (April 2011). DNR is failing to even adequately test for radioactivity and therefore, will not know the levels of radioactivity. How, then, can

## Fair Economy Illinois

---

DNR adequately protect workers and the general public? Elaboration: IDNR does not define a Fixed Date ( $\pm X$  days) for testing. Day 1, <Hour 1 test results will be orders of magnitude lower than either Day 2 or Day 10 tests results, and Day 10 tests results will be significantly lower than Day 80 ( $\pm 7$  days) results. Failure to specify a Fixed Test Date ( $\pm X$  days) renders test data so many irrelevant apples and oranges and allows companies to report suppressed, meaningless results by reporting Day 1, < 1 Hour data. The figure below, provided by the USGS, illustrates the nature of the problem. Please note that radium is not tested at Day 1, < 1 Hour. However, radium coprecipitates with barium, which is represented in total dissolved solids (TDS). It will therefore track TDS fairly closely. Conclusion: companies will be testing the very first flowback water to emerge from a fracked well. It will be Day 1, Minute 1 test results. 2.) There are two pits on a frack pad, one for "emergency" flowback and another, smaller one for drill cuttings and drilling mud. It is a basic principle in horizontal fracking to steer the drill bit through the horizontal strata with the highest gamma radiation readings (GAPI logs). The reason is that radioactivity correlates highly with total organic content (TOC) in the rock, and TOC correlates highly with oil and gas yields. This means that rock cuttings in the smaller drill mud and cuttings frack pit will often be more radioactive than flowback water. The IDNR knows this; yet it does not call for testing of drill bit pits as allowed under the Powers and duties section of the Act (§1- 15). 3.) The term "adjacent to" requires a "precise, clear standard" [IAPA, §100/5-20]. None is given. Does "adjacent to" mean 6 inches, 16 inches, 6 feet, 16 feet, or 60 feet? The IDNR does not say. 4.) Frack pad pipes and equipment can become incredibly radioactive over time. The very large temperature and pressure drops, as fluids move to the surface from thousands of feet underground, means that aqueous radioactive salts precipitate out as scale on pipes and equipment. The levels of radioactivity in pipe scale can exceed 100,000 picoCuries per gram and constitute a hazard to workers, or others who are exposed to recycled scrap metal from gas and oil operations. Yet, IDNR does not call on its General Assembly deferred "Power and authority" [Act, §1-15(e)] to test pipe, tanks, sludge, and equipment. This issue has been an issue in the oil and gas industry since the 1980s. We should prevent these problem from the start. Cleanup, after the oil and gas industry is gone, will be dreadfully expensive.. Recommendations: 1. Define the test date as = Day 21, the point at which increases in test results begin to level off. 2. Test for "radioactivity" in (1) flowback/produced water, (2) drill cuttings, soil "adjacent to" (3) storage tanks and (4) reserve pits, and (5) pipes and well pad equipment. 3. Define "adjacent to" as between 6 and 12 inches with test samples to be taken within the top 6 inches of soil 4. The rules should also require that the requirements of the Illinois Low Level Radioactivity Waste Management Act be followed.

Sincerely, Vadim Tanyoin Chicago, IL 60637

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Act §1-75(a)7 requires radioactivity testing "once per well site" for (1) flowback water and ground "adjacent to" (2) storage tanks and (3) reserve pits. Act § 1-120 requires IDNR compliance with all "applicable federal, State, and local laws." One applicable State law is the Illinois Low-Level Radioactive Waste Management Act (PA 83-991 / 420ILCS20). Another is the Occupational Health and Safety Administration (OSHA) standards for workplace safety in settings with exposure to radioactivity (29 CFR 1910.1096). Rules §245.850(d)1-E and §245.850(e) are incomplete and deficient, and these inadequacies can "constitute a serious threat"--indeed, deadly threat-- "to the public interest, safety, or welfare" of Illinois citizens." Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Notably absent from these proposed rules is a requirement for the testing of "produced water", the fluid that returns from the well during the later stage of production (after flowback). Under the proposed rules, "produced water" can be stored on site and/or can be "recycled", yet there is no testing requirement. Naturally occurring radioactive material (NORM) is found in "produced water" also. See Technologically enhanced naturally occurring radioactive materials in the oil industry (TENORM), Nukleonika 2009; 54(1):3-9, and sources cited therein, especially for TENORM in produced water in the U.S., available at [http://www.nukleonika.pl/www/back/full/vol54\\_2009/v54n1p003f.pdf](http://www.nukleonika.pl/www/back/full/vol54_2009/v54n1p003f.pdf). See also NORM is also found on scale in oil pipes and on fracking equipment. (See Kentucky Resources Council Proposes Comprehensive Plan For Investigating Radiological Contamination In Martha Oil Field. August 11, 2005. <http://www.kyrc.org/webnewspro/112381723236086.shtml>.) IDNR's definitions of "flowback water" and "produced water" are different. The two are distinguishably different enough that they are treated as separate types of fluid by both the Hydraulic Fracturing Regulatory Act and by the DNR Rules. Discharge of produced water onto the ground or into surface water or water drainage way is prohibited but it is not tested for radioactivity. This despite the fact that this fluid will be in contact with the naturally occurring radioactive elements in the ground for a longer period than the flowback and that it is much more likely to be radioactive. Problems: Failure to test produced water for radioactivity is problematic for a variety of reasons including: The health and safety of workers on the site who will be unaware of the levels of radioactivity they are being exposed to. The health and safety of workers transporting produced water who will also be in the dark regarding the levels of radioactivity they will be exposed to. The risk of storing radioactive material in tanks not created for storing radioactive materials. The risk of "recycling" produced water—radioactivity cannot be removed by recycling. The risk to the public in transporting radioactive materials Argonne National Laboratory recently cautioned about radiological doses: "It is commonly accepted that efforts should be undertaken at all times to keep radiological doses 'as low as reasonably achievable,' which is referred to as the ALARA principle or requirement." Overview of Radiological Dose and Risk Assessment (April 2011). DNR is failing to even adequately test for radioactivity and therefore, will not know the levels of radioactivity. How, then, can

## Fair Economy Illinois

---

DNR adequately protect workers and the general public? Elaboration: IDNR does not define a Fixed Date ( $\pm X$  days) for testing. Day 1, <Hour 1 test results will be orders of magnitude lower than either Day 2 or Day 10 tests results, and Day 10 tests results will be significantly lower than Day 80 ( $\pm 7$  days) results. Failure to specify a Fixed Test Date ( $\pm X$  days) renders test data so many irrelevant apples and oranges and allows companies to report suppressed, meaningless results by reporting Day 1, < 1 Hour data. The figure below, provided by the USGS, illustrates the nature of the problem. Please note that radium is not tested at Day 1, < 1 Hour. However, radium coprecipitates with barium, which is represented in total dissolved solids (TDS). It will therefore track TDS fairly closely. Conclusion: companies will be testing the very first flowback water to emerge from a fracked well. It will be Day 1, Minute 1 test results. 2.) There are two pits on a frack pad, one for "emergency" flowback and another, smaller one for drill cuttings and drilling mud. It is a basic principle in horizontal fracking to steer the drill bit through the horizontal strata with the highest gamma radiation readings (GAPI logs). The reason is that radioactivity correlates highly with total organic content (TOC) in the rock, and TOC correlates highly with oil and gas yields. This means that rock cuttings in the smaller drill mud and cuttings frack pit will often be more radioactive than flowback water. The IDNR knows this; yet it does not call for testing of drill bit pits as allowed under the Powers and duties section of the Act (§1- 15). 3.) The term "adjacent to" requires a "precise, clear standard" [IAPA, §100/5-20]. None is given. Does "adjacent to" mean 6 inches, 16 inches, 6 feet, 16 feet, or 60 feet? The IDNR does not say. 4.) Frack pad pipes and equipment can become incredibly radioactive over time. The very large temperature and pressure drops, as fluids move to the surface from thousands of feet underground, means that aqueous radioactive salts precipitate out as scale on pipes and equipment. The levels of radioactivity in pipe scale can exceed 100,000 picoCuries per gram and constitute a hazard to workers, or others who are exposed to recycled scrap metal from gas and oil operations. Yet, IDNR does not call on its General Assembly deferred "Power and authority" [Act, §1-15(e)] to test pipe, tanks, sludge, and equipment. This issue has been an issue in the oil and gas industry since the 1980s. Consequences: According to studies by the Illinois State Geological Survey, the Illinois New Albany Shale Formation, the source rock for our oil and gas reserves, has above average levels of uranium (29 ppm). Uranium decays into radium and thence radon. Both uranium and radium are water soluble. As noted, the U.S. Geological Survey has found oil field brine or produced water in Southern Illinois to have Radium226 levels that average more than 1,000 picoCuries / liter (USGS 1999). That reading is 67 times above the maximum contamination level of the EPA. Radium226 has a half life of 1,600 years. Uranium228 has a half life of 4.468 billion years. If these water soluble salts leach into our aquifers, nearby communities will require--if possible--very expensive water treatment for the next 1,000 years. We may have to return to rainwater harvesting with the modern equivalent of cisterns. The radioactive levels for produced water from shale gas operations are likely to be 2 to 4 times higher than oilfield brine -- on average, 2,000 to 4,000 picoCuries per liter. In addition, radon levels in methane, propane, and ethane can be dangerously high. When it becomes commercial to extract shale gas from the SE corner of the state, major markets, such as Springfield and Chicago, will only be 0.9 and 1.4 days removed from shale gas wellheads. Even though radon222 has a half life of only 3.8 days, the closeness of major Illinois retail gas markets will mean that large number of people will be breathing in high levels of radon when they cook meals. The average level of indoor exposure to radon in Illinois is already 4.4

## Fair Economy Illinois

---

pCi/L ( American Lung Association 2013). The EPA maximum level--the point at which corrective action should be taken--is 4.0 pCi/L, and the preferred level is =3.0 pCi/L. The turn to shale gas, with its high levels of radon, will also turn a major Illinois public health problem in the wrong direction. Radioactive scale in pipe and equipment presents another problem; high levels of radioactivity have been found in school playground equipment and bleachers in school sports stadiums in Mississippi and Texas. Do we want untested oil and gas field scrap metal sold into Illinois markets? Do we want our children exposed on a daily basis to radioactive metal? The present rules creates no barriers to such an outcome. The problems cited above are why Illinois, with its large number of nuclear power plants, has a Low-Level Radioactive Waste Management Act. It and OSHA are the applicable State and Federal agencies with respect to the issue of radioactive waste and work safety standards in settings with exposure to radioactivity. If we faithfully follow applicable State and federal laws, Illinois can minimize the pernicious problems other states are going to face from the uncontrolled release of radioactive elements into their water and soil and work and non-work settings. We should prevent these problem from the start. Cleanup, after the oil and gas industry is gone, will be dreadfully expensive.. Recommendations: 1. Define the test date as = Day 21, the point at which increases in test results begin to level off. 2. Test for "radioactivity" in (1) flowback/produced water, (2) drill cuttings, soil "adjacent to" (3) storage tanks and (4) reserve pits, and (5) pipes and well pad equipment. 3. Define "adjacent to" as between 6 and 12 inches with test samples to be taken within the top 6 inches of soil 4. The rules should also require that the requirements of the Illinois Low Level Radioactivity Waste Management Act be followed.

Sincerely, Vadim Tanyoin Chicago, IL 60637

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Act §1-75(a)7 requires radioactivity testing "once per well site" for (1) flowback water and ground "adjacent to" (2) storage tanks and (3) reserve pits. Act § 1-120 requires IDNR compliance with all "applicable federal, State, and local laws." One applicable State law is the Illinois Low-Level Radioactive Waste Management Act (PA 83-991 / 420ILCS20). Another is the Occupational Health and Safety Administration (OSHA) standards for workplace safety in settings with exposure to radioactivity (29 CFR 1910.1096). Rules §245.850(d)1-E and §245.850(e) are incomplete and deficient, and these inadequacies can "constitute a serious threat"--indeed, deadly threat-- "to the public interest, safety, or welfare" of Illinois citizens." Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Notably absent from these proposed rules is a requirement for the testing of "produced water", the fluid that returns from the well during the later stage of production (after flowback). Under the proposed rules, "produced water" can be stored on site and/or can be "recycled", yet there is no testing requirement. Naturally occurring radioactive material (NORM) is found in "produced water" also. See Technologically enhanced naturally occurring radioactive materials in the oil industry (TENORM), Nukleonika 2009; 54(1):3-9, and sources cited therein, especially for TENORM in produced water in the U.S., available at [http://www.nukleonika.pl/www/back/full/vol54\\_2009/v54n1p003f.pdf](http://www.nukleonika.pl/www/back/full/vol54_2009/v54n1p003f.pdf). See also NORM is also found on scale in oil pipes and on fracking equipment. (See Kentucky Resources Council Proposes Comprehensive Plan For Investigating Radiological Contamination In Martha Oil Field. August 11, 2005. <http://www.kyrc.org/webnewspro/112381723236086.shtml>.) IDNR's definitions of "flowback water" and "produced water" are different. The two are distinguishably different enough that they are treated as separate types of fluid by both the Hydraulic Fracturing Regulatory Act and by the DNR Rules. Discharge of produced water onto the ground or into surface water or water drainage way is prohibited but it is not tested for radioactivity. This despite the fact that this fluid will be in contact with the naturally occurring radioactive elements in the ground for a longer period than the flowback and that it is much more likely to be radioactive. Problems: Failure to test produced water for radioactivity is problematic for a variety of reasons including: The health and safety of workers on the site who will be unaware of the levels of radioactivity they are being exposed to. The health and safety of workers transporting produced water who will also be in the dark regarding the levels of radioactivity they will be exposed to. The risk of storing radioactive material in tanks not created for storing radioactive materials. The risk of "recycling" produced water—radioactivity cannot be removed by recycling. The risk to the public in transporting radioactive materials Argonne National Laboratory recently cautioned about radiological doses: "It is commonly accepted that efforts should be undertaken at all times to keep radiological doses 'as low as reasonably achievable,' which is referred to as the ALARA principle or requirement." Overview of Radiological Dose and Risk Assessment (April 2011). DNR is failing to even adequately test for radioactivity and therefore, will not know the levels of radioactivity. How, then, can

## Fair Economy Illinois

---

DNR adequately protect workers and the general public? Elaboration: IDNR does not define a Fixed Date ( $\pm X$  days) for testing. Day 1, <Hour 1 test results will be orders of magnitude lower than either Day 2 or Day 10 tests results, and Day 10 tests results will be significantly lower than Day 80 ( $\pm 7$  days) results. Failure to specify a Fixed Test Date ( $\pm X$  days) renders test data so many irrelevant apples and oranges and allows companies to report suppressed, meaningless results by reporting Day 1, < 1 Hour data. The figure below, provided by the USGS, illustrates the nature of the problem. Please note that radium is not tested at Day 1, < 1 Hour. However, radium coprecipitates with barium, which is represented in total dissolved solids (TDS). It will therefore track TDS fairly closely. Conclusion: companies will be testing the very first flowback water to emerge from a fracked well. It will be Day 1, Minute 1 test results. 2.) There are two pits on a frack pad, one for "emergency" flowback and another, smaller one for drill cuttings and drilling mud. It is a basic principle in horizontal fracking to steer the drill bit through the horizontal strata with the highest gamma radiation readings (GAPI logs). The reason is that radioactivity correlates highly with total organic content (TOC) in the rock, and TOC correlates highly with oil and gas yields. This means that rock cuttings in the smaller drill mud and cuttings frack pit will often be more radioactive than flowback water. The IDNR knows this; yet it does not call for testing of drill bit pits as allowed under the Powers and duties section of the Act (§1- 15). 3.) The term "adjacent to" requires a "precise, clear standard" [IAPA, §100/5-20]. None is given. Does "adjacent to" mean 6 inches, 16 inches, 6 feet, 16 feet, or 60 feet? The IDNR does not say. 4.) Frack pad pipes and equipment can become incredibly radioactive over time. The very large temperature and pressure drops, as fluids move to the surface from thousands of feet underground, means that aqueous radioactive salts precipitate out as scale on pipes and equipment. The levels of radioactivity in pipe scale can exceed 100,000 picoCuries per gram and constitute a hazard to workers, or others who are exposed to recycled scrap metal from gas and oil operations. Yet, IDNR does not call on its General Assembly deferred "Power and authority" [Act, §1-15(e)] to test pipe, tanks, sludge, and equipment. This issue has been an issue in the oil and gas industry since the 1980s. Consequences: According to studies by the Illinois State Geological Survey, the Illinois New Albany Shale Formation, the source rock for our oil and gas reserves, has above average levels of uranium (29 ppm). Uranium decays into radium and thence radon. Both uranium and radium are water soluble. As noted, the U.S. Geological Survey has found oil field brine or produced water in Southern Illinois to have Radium226 levels that average more than 1,000 picoCuries / liter (USGS 1999). That reading is 67 times above the maximum contamination level of the EPA. Radium226 has a half life of 1,600 years. Uranium228 has a half life of 4.468 billion years. If these water soluble salts leach into our aquifers, nearby communities will require--if possible--very expensive water treatment for the next 1,000 years. We may have to return to rainwater harvesting with the modern equivalent of cisterns. The radioactive levels for produced water from shale gas operations are likely to be 2 to 4 times higher than oilfield brine -- on average, 2,000 to 4,000 picoCuries per liter. In addition, radon levels in methane, propane, and ethane can be dangerously high. When it becomes commercial to extract shale gas from the SE corner of the state, major markets, such as Springfield and Chicago, will only be 0.9 and 1.4 days removed from shale gas wellheads. Even though radon222 has a half life of only 3.8 days, the closeness of major Illinois retail gas markets will mean that large number of people will be breathing in high levels of radon when they cook meals. The average level of indoor exposure to radon in Illinois is already 4.4

## Fair Economy Illinois

---

pCi/L ( American Lung Association 2013). The EPA maximum level--the point at which corrective action should be taken--is 4.0 pCi/L, and the preferred level is =3.0 pCi/L. The turn to shale gas, with its high levels of radon, will also turn a major Illinois public health problem in the wrong direction. Radioactive scale in pipe and equipment presents another problem; high levels of radioactivity have been found in school playground equipment and bleachers in school sports stadiums in Mississippi and Texas. Do we want untested oil and gas field scrap metal sold into Illinois markets? Do we want our children exposed on a daily basis to radioactive metal? The present rules creates no barriers to such an outcome. The problems cited above are why Illinois, with its large number of nuclear power plants, has a Low-Level Radioactive Waste Management Act. It and OSHA are the applicable State and Federal agencies with respect to the issue of radioactive waste and work safety standards in settings with exposure to radioactivity. If we faithfully follow applicable State and federal laws, Illinois can minimize the pernicious problems other states are going to face from the uncontrolled release of radioactive elements into their water and soil and work and non-work settings. We should prevent these problem from the start. Cleanup, after the oil and gas industry is gone, will be dreadfully expensive.. Recommendations: 1. Define the test date as = Day 21, the point at which increases in test results begin to level off. 2. Test for "radioactivity" in (1) flowback/produced water, (2) drill cuttings, soil "adjacent to" (3) storage tanks and (4) reserve pits, and (5) pipes and well pad equipment. 3. Define "adjacent to" as between 6 and 12 inches with test samples to be taken within the top 6 inches of soil 4. The rules should also require that the requirements of the Illinois Low Level Radioactivity Waste Management Act be followed.

Sincerely, Will Fernandez Chicago, IL 60615

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Act §1-75(a)7 requires radioactivity testing "once per well site" for (1) flowback water and ground "adjacent to" (2) storage tanks and (3) reserve pits. Act § 1-120 requires IDNR compliance with all "applicable federal, State, and local laws." One applicable State law is the Illinois Low-Level Radioactive Waste Management Act (PA 83-991 / 420ILCS20). Another is the Occupational Health and Safety Administration (OSHA) standards for workplace safety in settings with exposure to radioactivity (29 CFR 1910.1096). Rules §245.850(d)1-E and §245.850(e) are incomplete and deficient, and these inadequacies can "constitute a serious threat"--indeed, deadly threat-- "to the public interest, safety, or welfare" of Illinois citizens." Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Notably absent from these proposed rules is a requirement for the testing of "produced water", the fluid that returns from the well during the later stage of production (after flowback). Under the proposed rules, "produced water" can be stored on site and/or can be "recycled", yet there is no testing requirement. Naturally occurring radioactive material (NORM) is found in "produced water" also. See Technologically enhanced naturally occurring radioactive materials in the oil industry (TENORM), Nukleonika 2009; 54(1):3-9, and sources cited therein, especially for TENORM in produced water in the U.S., available at [http://www.nukleonika.pl/www/back/full/vol54\\_2009/v54n1p003f.pdf](http://www.nukleonika.pl/www/back/full/vol54_2009/v54n1p003f.pdf). See also NORM is also found on scale in oil pipes and on fracking equipment. (See Kentucky Resources Council Proposes Comprehensive Plan For Investigating Radiological Contamination In Martha Oil Field. August 11, 2005. <http://www.kyrc.org/webnewspro/112381723236086.shtml>.) IDNR's definitions of "flowback water" and "produced water" are different. DNR adequately protect workers and the general public? Elaboration: IDNR does not define a Fixed Date ( $\pm X$  days) for testing. Day 1, <Hour 1 test results will be orders of magnitude lower than either Day 2 or Day 10 tests results, and Day 10 tests results will be significantly lower than Day 80 ( $\pm 7$  days) results. Failure to specify a Fixed Test Date ( $\pm X$  days) renders test data so many irrelevant apples and oranges and allows companies to report suppressed, meaningless results by reporting Day 1, < 1 Hour data. The figure below, provided by the USGS, illustrates the nature of the problem. Please note that radium is not tested at Day 1, < 1 Hour. However, radium coprecipitates with barium, which is represented in total dissolved solids (TDS). It will therefore track TDS fairly closely. Conclusion: companies will be testing the very first flowback water to emerge from a fracked well. It will be Day 1, Minute 1 test results. 2.) There are two pits on a frack pad, one for "emergency" flowback and another, smaller one for drill cuttings and drilling mud. It is a basic principle in horizontal fracking to steer the drill bit through the horizontal strata with the highest gamma radiation readings (GAPI logs). The reason is that radioactivity correlates highly with total organic content (TOC) in the rock, and TOC correlates highly with oil and gas yields. This means that rock cuttings in the smaller drill mud and cuttings frack pit will often be more radioactive than flowback water. The IDNR knows this; yet it does not call for testing of drill bit pits as allowed under the Powers and duties section of the Act (§1- 15). 3.) The term "adjacent to" requires a "precise, clear standard" [IAPA, §100/5-20]. None is given. Does "adjacent to" mean 6 inches, 16 inches, 6 feet, 16 feet, or 60 feet? The IDNR does not say. 4.) Frack pad pipes and equipment can become incredibly radioactive over time. The very large temperature and pressure drops, as fluids move to the surface from thousands of feet underground, means that aqueous radioactive salts precipitate out as scale on pipes and equipment. The levels of radioactivity in pipe scale can exceed 100,000 picoCuries per gram and constitute a hazard to workers, or others who are exposed to recycled scrap metal from gas and oil operations. Yet, IDNR does not call on its General Assembly deferred "Power and authority" [Act, §1-15(e)] to test pipe, tanks, sludge, and equipment. This issue has been an issue in the oil and gas industry since the 1980s. Consequences: According to studies by the Illinois State Geological Survey, the Illinois New Albany Shale Formation, the source rock for our oil and gas reserves, has above average levels of uranium (29 ppm). Uranium decays into radium and thence radon. Both uranium and radium are water soluble. As noted, the U.S. Geological Survey has found oil field brine or produced water in Southern Illinois to have Radium226 levels that average more than 1,000 picoCuries / liter (USGS 1999). That reading is 67 times above the maximum contamination level of the EPA. Radium226 has a half life of 1,600 years. Uranium228 has a half life of 4.468 billion years. If these water soluble salts leach into our aquifers, nearby communities will require--if possible--very expensive water treatment for the next 1,000 years. We may have to return to rainwater harvesting with the modern equivalent of cisterns. The radioactive levels for produced water from shale gas operations are likely to be 2 to 4 times higher than oilfield brine -- on average, 2,000 to 4,000 picoCuries per liter. In addition, radon levels in methane, propane, and ethane can be dangerously high. When it becomes commercial to extract shale gas from the SE corner of the state, major markets, such as Springfield and Chicago, will only be 0.9 and 1.4 days removed from shale gas wellheads. Even though radon222 has a half life of only 3.8 days, the closeness of major Illinois retail gas markets will mean that large number of people will be breathing in high levels of radon when they cook meals. The average level of indoor exposure to radon in Illinois is already 4.4

## Fair Economy Illinois

---

pCi/L ( American Lung Association 2013). The EPA maximum level--the point at which corrective action should be taken--is 4.0 pCi/L, and the preferred level is =3.0 pCi/L. The turn to shale gas, with its high levels of radon, will also turn a major Illinois public health problem in the wrong direction. Radioactive scale in pipe and equipment presents another problem; high levels of radioactivity have been found in school playground equipment and bleachers in school sports stadiums in Mississippi and Texas. Do we want untested oil and gas field scrap metal sold into Illinois markets? Do we want our children exposed on a daily basis to radioactive metal? The present rules creates no barriers to such an outcome. The problems cited above are why Illinois, with its large number of nuclear power plants, has a Low-Level Radioactive Waste Management Act. It and OSHA are the applicable State and Federal agencies with respect to the issue of radioactive waste and work safety standards in settings with exposure to radioactivity. If we faithfully follow applicable State and federal laws, Illinois can minimize the pernicious problems other states are going to face from the uncontrolled release of radioactive elements into their water and soil and work and non-work settings. We should prevent these problem from the start. Cleanup, after the oil and gas industry is gone, will be dreadfully expensive.. Recommendations: 1. Define the test date as = Day 21, the point at which increases in test results begin to level off. 2. Test for "radioactivity" in (1) flowback/produced water, (2) drill cuttings, soil "adjacent to" (3) storage tanks and (4) reserve pits, and (5) pipes and well pad equipment. 3. Define "adjacent to" as between 6 and 12 inches with test samples to be taken within the top 6 inches of soil 4. The rules should also require that the requirements of the Illinois Low Level Radioactivity Waste Management Act be followed.

Sincerely, William LaBounty Chicago, IL 60615

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Act §1-75(a)7 requires radioactivity testing "once per well site" for (1) flowback water and ground "adjacent to" (2) storage tanks and (3) reserve pits. Act § 1-120 requires IDNR compliance with all "applicable federal, State, and local laws." One applicable State law is the Illinois Low-Level Radioactive Waste Management Act (PA 83-991 / 420ILCS20). Another is the Occupational Health and Safety Administration (OSHA) standards for workplace safety in settings with exposure to radioactivity (29 CFR 1910.1096). Rules §245.850(d)1-E and §245.850(e) are incomplete and deficient, and these inadequacies can "constitute a serious threat"--indeed, deadly threat-- "to the public interest, safety, or welfare" of Illinois citizens." Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Notably absent from these proposed rules is a requirement for the testing of "produced water", the fluid that returns from the well during the later stage of production (after flowback). Under the proposed rules, "produced water" can be stored on site and/or can be "recycled", yet there is no testing requirement. Naturally occurring radioactive material (NORM) is found in "produced water" also. See Technologically enhanced naturally occurring radioactive materials in the oil industry (TENORM), Nukleonika 2009; 54(1):3-9, and sources cited therein, especially for TENORM in produced water in the U.S., available at [http://www.nukleonika.pl/www/back/full/vol54\\_2009/v54n1p003f.pdf](http://www.nukleonika.pl/www/back/full/vol54_2009/v54n1p003f.pdf). See also NORM is also found on scale in oil pipes and on fracking equipment. (See Kentucky Resources Council Proposes Comprehensive Plan For Investigating Radiological Contamination In Martha Oil Field. August 11, 2005. <http://www.kyrc.org/webnewspro/112381723236086.shtml>.) IDNR's definitions of "flowback water" and "produced water" are different. The two are distinguishably different enough that they are treated as separate types of fluid by both the Hydraulic Fracturing Regulatory Act and by the DNR Rules. Discharge of produced water onto the ground or into surface water or water drainage way is prohibited but it is not tested for radioactivity. This despite the fact that this fluid will be in contact with the naturally occurring radioactive elements in the ground for a longer period than the flowback and that it is much more likely to be radioactive. Problems: Failure to test produced water for radioactivity is problematic for a variety of reasons including: The health and safety of workers on the site who will be unaware of the levels of radioactivity they are being exposed to. The health and safety of workers transporting produced water who will also be in the dark regarding the levels of radioactivity they will be exposed to. The risk of storing radioactive material in tanks not created for storing radioactive materials. The risk of "recycling" produced water—radioactivity cannot be removed by recycling. The risk to the public in transporting radioactive materials Argonne National Laboratory recently cautioned about radiological doses: "It is commonly accepted that efforts should be undertaken at all times to keep radiological doses 'as low as reasonably achievable,' which is referred to as the ALARA principle or requirement." Overview of Radiological Dose and Risk Assessment (April 2011). DNR is failing to even adequately test for radioactivity and therefore, will not know the levels of radioactivity. How, then, can

## Fair Economy Illinois

---

DNR adequately protect workers and the general public? Elaboration: IDNR does not define a Fixed Date ( $\pm X$  days) for testing. Day 1, <Hour 1 test results will be orders of magnitude lower than either Day 2 or Day 10 tests results, and Day 10 tests results will be significantly lower than Day 80 ( $\pm 7$  days) results. Failure to specify a Fixed Test Date ( $\pm X$  days) renders test data so many irrelevant apples and oranges and allows companies to report suppressed, meaningless results by reporting Day 1, < 1 Hour data. The figure below, provided by the USGS, illustrates the nature of the problem. Please note that radium is not tested at Day 1, < 1 Hour. However, radium coprecipitates with barium, which is represented in total dissolved solids (TDS). It will therefore track TDS fairly closely. Conclusion: companies will be testing the very first flowback water to emerge from a fracked well. It will be Day 1, Minute 1 test results. 2.) There are two pits on a frack pad, one for "emergency" flowback and another, smaller one for drill cuttings and drilling mud. It is a basic principle in horizontal fracking to steer the drill bit through the horizontal strata with the highest gamma radiation readings (GAPI logs). The reason is that radioactivity correlates highly with total organic content (TOC) in the rock, and TOC correlates highly with oil and gas yields. This means that rock cuttings in the smaller drill mud and cuttings frack pit will often be more radioactive than flowback water. The IDNR knows this; yet it does not call for testing of drill bit pits as allowed under the Powers and duties section of the Act (§1- 15). 3.) The term "adjacent to" requires a "precise, clear standard" [IAPA, §100/5-20]. None is given. Does "adjacent to" mean 6 inches, 16 inches, 6 feet, 16 feet, or 60 feet? The IDNR does not say. 4.) Frack pad pipes and equipment can become incredibly radioactive over time. pCi/L ( American Lung Association 2013). The EPA maximum level--the point at which corrective action should be taken--is 4.0 pCi/L, and the preferred level is =3.0 pCi/L. The turn to shale gas, with its high levels of radon, will also turn a major Illinois public health problem in the wrong direction. Radioactive scale in pipe and equipment presents another problem; high levels of radioactivity have been found in school playground equipment and bleachers in school sports stadiums in Mississippi and Texas. Do we want untested oil and gas field scrap metal sold into Illinois markets? Do we want our children exposed on a daily basis to radioactive metal? The present rules creates no barriers to such an outcome. The problems cited above are why Illinois, with its large number of nuclear power plants, has a Low-Level Radioactive Waste Management Act. It and OSHA are the applicable State and Federal agencies with respect to the issue of radioactive waste and work safety standards in settings with exposure to radioactivity. If we faithfully follow applicable State and federal laws, Illinois can minimize the pernicious problems other states are going to face from the uncontrolled release of radioactive elements into their water and soil and work and non-work settings. We should prevent these problem from the start. Cleanup, after the oil and gas industry is gone, will be dreadfully expensive.. Recommendations: 1. Define the test date as = Day 21, the point at which increases in test results begin to level off. 2. Test for "radioactivity" in (1) flowback/produced water, (2) drill cuttings, soil "adjacent to" (3) storage tanks and (4) reserve pits, and (5) pipes and well pad equipment. 3. Define "adjacent to" as between 6 and 12 inches with test samples to be taken within the top 6 inches of soil 4. The rules should also require that the requirements of the Illinois Low Level Radioactivity Waste Management Act be followed.

Sincerely, Zach Taylor Chicago, IL 60637

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Act §1-75(a)7 requires radioactivity testing "once per well site" for (1) flowback water and ground "adjacent to" (2) storage tanks and (3) reserve pits. Act § 1-120 requires IDNR compliance with all "applicable federal, State, and local laws." One applicable State law is the Illinois Low-Level Radioactive Waste Management Act (PA 83-991 / 420ILCS20). Another is the Occupational Health and Safety Administration (OSHA) standards for workplace safety in settings with exposure to radioactivity (29 CFR 1910.1096). Rules §245.850(d)1-E and §245.850(e) are incomplete and deficient, and these inadequacies can "constitute a serious threat"--indeed, deadly threat-- "to the public interest, safety, or welfare" of Illinois citizens." Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Notably absent from these proposed rules is a requirement for the testing of "produced water", the fluid that returns from the well during the later stage of production (after flowback). Under the proposed rules, "produced water" can be stored on site and/or can be "recycled", yet there is no testing requirement. Naturally occurring radioactive material (NORM) is found in "produced water" also. See Technologically enhanced naturally occurring radioactive materials in the oil industry (TENORM), Nukleonika 2009; 54(1):3-9, and sources cited therein, especially for TENORM in produced water in the U.S., available at [http://www.nukleonika.pl/www/back/full/vol54\\_2009/v54n1p003f.pdf](http://www.nukleonika.pl/www/back/full/vol54_2009/v54n1p003f.pdf). See also NORM is also found on scale in oil pipes and on fracking equipment. (See Kentucky Resources Council Proposes Comprehensive Plan For Investigating Radiological Contamination In Martha Oil Field. August 11, 2005. <http://www.kyrc.org/webnewspro/112381723236086.shtml>.) IDNR's definitions of "flowback water" and "produced water" are different. The two are distinguishably different enough that they are treated as separate types of fluid by both the Hydraulic Fracturing Regulatory Act and by the DNR Rules. Discharge of produced water onto the ground or into surface water or water drainage way is prohibited but it is not tested for radioactivity. This despite the fact that this fluid will be in contact with the naturally occurring radioactive elements in the ground for a longer period than the flowback and that it is much more likely to be radioactive. Problems: Failure to test produced water for radioactivity is problematic for a variety of reasons including: The health and safety of workers on the site who will be unaware of the levels of radioactivity they are being exposed to. The health and safety of workers transporting produced water who will also be in the dark regarding the levels of radioactivity they will be exposed to. The risk of storing radioactive material in tanks not created for storing radioactive materials. The risk of "recycling" produced water—radioactivity cannot be removed by recycling. The risk to the public in transporting radioactive materials Argonne National Laboratory recently cautioned about radiological doses: "It is commonly accepted that efforts should be undertaken at all times to keep radiological doses 'as low as reasonably achievable,' which is referred to as the ALARA principle or requirement." Overview of Radiological Dose and Risk Assessment (April 2011). DNR is failing to even adequately test for radioactivity and therefore, will not know the levels of radioactivity. How, then, can

## Fair Economy Illinois

---

DNR adequately protect workers and the general public? Elaboration: IDNR does not define a Fixed Date ( $\pm X$  days) for testing. Day 1, <Hour 1 test results will be orders of magnitude lower than either Day 2 or Day 10 tests results, and Day 10 tests results will be significantly lower than Day 80 ( $\pm 7$  days) results. Failure to specify a Fixed Test Date ( $\pm X$  days) renders test data so many irrelevant apples and oranges and allows companies to report suppressed, meaningless results by reporting Day 1, < 1 Hour data. The figure below, provided by the USGS, illustrates the nature of the problem. Please note that radium is not tested at Day 1, < 1 Hour. However, radium coprecipitates with barium, which is represented in total dissolved solids (TDS). It will therefore track TDS fairly closely. Conclusion: companies will be testing the very first flowback water to emerge from a fracked well. It will be Day 1, Minute 1 test results. 2.) There are two pits on a frack pad, one for "emergency" flowback and another, smaller one for drill cuttings and drilling mud. It is a basic principle in horizontal fracking to steer the drill bit through the horizontal strata with the highest gamma radiation readings (GAPI logs). The reason is that radioactivity correlates highly with total organic content (TOC) in the rock, and TOC correlates highly with oil and gas yields. This means that rock cuttings in the smaller drill mud and cuttings frack pit will often be more radioactive than flowback water. The IDNR knows this; yet it does not call for testing of drill bit pits as allowed under the Powers and duties section of the Act (§1- 15). 3.) The term "adjacent to" requires a "precise, clear standard" [IAPA, §100/5-20]. None is given. Does "adjacent to" mean 6 inches, 16 inches, 6 feet, 16 feet, or 60 feet? The IDNR does not say. 4.) Frack pad pipes and equipment can become incredibly radioactive over time. The very large temperature and pressure drops, as fluids move to the surface from thousands of feet underground, means that aqueous radioactive salts precipitate out as scale on pipes and equipment. The levels of radioactivity in pipe scale can exceed 100,000 picoCuries per gram and constitute a hazard to workers, or others who are exposed to recycled scrap metal from gas and oil operations. Yet, IDNR does not call on its General Assembly deferred "Power and authority" [Act, §1-15(e)] to test pipe, tanks, sludge, and equipment. This issue has been an issue in the oil and gas industry since the 1980s. Consequences: According to studies by the Illinois State Geological Survey, the Illinois New Albany Shale Formation, the source rock for our oil and gas reserves, has above average levels of uranium (29 ppm). Uranium decays into radium and thence radon. Both uranium and radium are water soluble. As noted, the U.S. Geological Survey has found oil field brine or produced water in Southern Illinois to have Radium226 levels that average more than 1,000 picoCuries / liter (USGS 1999). That reading is 67 times above the maximum contamination level of the EPA. Radium226 has a half life of 1,600 years. Uranium228 has a half life of 4.468 billion years. If these water soluble salts leach into our aquifers, nearby communities will require--if possible--very expensive water treatment for the next 1,000 years. We may have to return to rainwater harvesting with the modern equivalent of cisterns. The radioactive levels for produced water from shale gas operations are likely to be 2 to 4 times higher than oilfield brine -- on average, 2,000 to 4,000 picoCuries per liter. In addition, radon levels in methane, propane, and ethane can be dangerously high. When it becomes commercial to extract shale gas from the SE corner of the state, major markets, such as Springfield and Chicago, will only be 0.9 and 1.4 days removed from shale gas wellheads. Even though radon222 has a half life of only 3.8 days, the closeness of major Illinois retail gas markets will mean that large number of people will be breathing in high levels of radon when they cook meals. The average level of indoor exposure to radon in Illinois is already 4.4

## Fair Economy Illinois

---

pCi/L ( American Lung Association 2013). The EPA maximum level--the point at which corrective action should be taken--is 4.0 pCi/L, and the preferred level is =3.0 pCi/L. The turn to shale gas, with its high levels of radon, will also turn a major Illinois public health problem in the wrong direction. Radioactive scale in pipe and equipment presents another problem; high levels of radioactivity have been found in school playground equipment and bleachers in school sports stadiums in Mississippi and Texas. Do we want untested oil and gas field scrap metal sold into Illinois markets? Do we want our children exposed on a daily basis to radioactive metal? The present rules creates no barriers to such an outcome. The problems cited above are why Illinois, with its large number of nuclear power plants, has a Low-Level Radioactive Waste Management Act. In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

An 2011 article from the New York Times exposed the results of extensive review of "30,000 pages of federal, state and company records relating to more than 200 gas wells in Pennsylvania, 40 in West Virginia and 20 public and private wastewater treatment plants." They discovered, among other things, that: "Of more than 179 wells producing wastewater with high levels of radiation, at least 116 reported levels of radium or other radioactive materials 100 times as high as the levels set by federal drinking-water standards. At least 15 wells produced wastewater carrying more than 1,000 times the amount of radioactive elements considered acceptable." So is there a question that we should be testing both flowback and produced water? Without testing for radioactive elements in flowback and produced water, IDNR is placing the health and safety of workers both on-site and transporting the waste at risk, in violation of section 1-75(a)(2) of the Hydraulic Fracturing Regulatory Act. Moreover, if radiation levels, which can be significant, are unknown, there is the potential for storing the waste in containers ill-designed to contain such material, recycling radioactive material, exposing workers and transporters (who should be protected by OSHA) to radiation, and exposing the public to radioactive material via transport. Clearly, a historical, now rectified, lack of testing has not bode well for Pennsylvania, where a recent Duke study found that "[r]adium levels in samples collected at the [water treatment] facility were 200 times greater than samples taken upstream. Such elevated levels of radioactivity are above regulated levels and would normally be seen at licensed radioactive disposal facilities, according to the scientists at Duke University's Nicholas School of the Environment in North Carolina." (<http://www.theguardian.com/environment/2013/oct/02/dangerous-radioactivity-frackingwaste-pennsylvania>) If we don't test, we will never know, and that poses a significant risk to both Illinois citizens and the environment, which IDNR is charged to protect. IDNR should require that "produced water" be tested at two separate intervals across time for radioactivity, as now required in Pennsylvania. IDNR should also require that the Illinois Low Level Radioactivity Waste Management Act be followed with regards to radioactive material resulting from fracking. The taxpayer should not be stuck with the bill for cleanup, as has been seen in numerous other states where hydraulic fracturing has occurred.

Sincerely, Sara Buck Chicago , IL 60640

The two are distinguishably different enough that they are treated as separate types of fluid by both the Hydraulic Fracturing Regulatory Act and by the DNR Rules. Discharge of produced water onto the ground or into surface water or water drainage way is prohibited but it is not tested for radioactivity. This despite the fact that this fluid will be in contact with the naturally occurring radioactive elements in the ground for a longer period that the flowback and that it is much more likely to be radioactive. Problems: Failure to test produced water for radioactivity is problematic for a variety of reasons including: The health and safety of workers on the site who will be unaware of the levels of radioactivity they are being exposed to. The health and safety of workers transporting produced water who will also be in the dark regarding the levels of radioactivity they will be exposed to. The risk of storing radioactive material in tanks not created for storing radioactive materials. The risk of "recycling" produced water—radioactivity cannot be removed by recycling. The risk to the public in transporting radioactive materials Argonne National Laboratory recently cautioned about radiological doses: "It is commonly accepted that efforts should be undertaken at all times to keep radiological doses 'as low as reasonably achievable,' which is referred to as the ALARA principle or requirement." Overview of Radiological Dose and Risk Assessment (April 2011). DNR is failing to even adequately test for radioactivity and therefore, will not know the levels of radioactivity. How, then, can DNR adequately protect workers and the general public? Revisions needed: At a bare minimum, the rules should require that "produced water" be tested at two separate intervals across time for radioactivity. This is already required in Pennsylvania. The rules should also require that the requirements of the Illinois Low Level Radioactivity Waste Management Act be followed.

Sincerely, Ammar Kalimullah Chicago, IL 60637

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Comment/Problem(s)/Needed Revisions: Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Notably absent from these proposed rules is a requirement for the testing of "produced water", the fluid that returns from the well during the later stage of production (after flowback). Under the proposed rules, "produced water" can be stored on site and/or can be "recycled", yet there is no testing requirement. Naturally occurring radioactive material (NORM) is found in "produced water" also. See Technologically enhanced naturally occurring radioactive materials in the oil industry (TENORM), Nukleonika 2009; 54(1):3-9, and sources cited therein, especially for TENORM in produced water in the U.S., available at [http://www.nukleonika.pl/www/back/full/vol54\\_2009/v54n1p003f.pdf](http://www.nukleonika.pl/www/back/full/vol54_2009/v54n1p003f.pdf). See also NORM is also found on scale in oil pipes and on fracking equipment. (See Kentucky Resources Council Proposes Comprehensive Plan For Investigating Radiological Contamination In Martha Oil Field. August 11, 2005. <http://www.kyrc.org/webnewspro/112381723236086.shtml>.) IDNR's definitions of "flowback water" and "produced water" are different. The two are distinguishably different enough that they are treated as separate types of fluid by both the Hydraulic Fracturing Regulatory Act and by the DNR Rules. Discharge of produced water onto the ground or into surface water or water drainage way is prohibited but it is not tested for radioactivity. This despite the fact that this fluid will be in contact with the naturally occurring radioactive elements in the ground for a longer period than the flowback and that it is much more likely to be radioactive. Under the proposed rules, "produced water" can be stored on site and/or can be "recycled", yet there is no testing requirement. Naturally occurring radioactive material (NORM) is found in "produced water" also. See Technologically enhanced naturally occurring radioactive materials in the oil industry (TENORM), Nukleonika 2009; 54(1):3-9, and sources cited therein, especially for TENORM in produced water in the U.S., available at [http://www.nukleonika.pl/www/back/full/vol54\\_2009/v54n1p003f.pdf](http://www.nukleonika.pl/www/back/full/vol54_2009/v54n1p003f.pdf). See also NORM is also found on scale in oil pipes and on fracking equipment. (See Kentucky Resources Council Proposes Comprehensive Plan For Investigating Radiological Contamination In Martha Oil Field. August 11, 2005. <http://www.kyrc.org/webnewspro/112381723236086.shtml>.) IDNR's definitions of "flowback water" and "produced water" are different. The two are distinguishably different enough that they are treated as separate types of fluid by both the Hydraulic Fracturing Regulatory Act and by the DNR Rules. Discharge of produced water onto the ground or into surface water or water drainage way is prohibited but it is not tested for radioactivity. This despite the fact that this fluid will be in contact with the naturally occurring radioactive elements in the ground for a longer period than the flowback and that it is much more likely to be radioactive. Problems: Failure to test produced water for radioactivity is problematic for a variety of reasons including: The health and safety of workers on the site who will be unaware of the levels of radioactivity they are being exposed to. The health and safety of workers transporting produced water who will also be in the dark regarding the levels of radioactivity they will be exposed to. The risk of storing radioactive material in tanks not created for storing radioactive materials. The risk of "recycling" produced water—radioactivity cannot be removed by recycling. The risk to the public in transporting radioactive materials Argonne National Laboratory recently cautioned about radiological doses: "It is commonly accepted that efforts should be undertaken at all times to keep radiological doses 'as low as reasonably achievable,' which is referred to as the ALARA principle or requirement." Overview of Radiological Dose and Risk Assessment (April 2011). DNR is failing to even adequately test for radioactivity and therefore, will not know the levels of radioactivity. How, then, can DNR adequately protect workers and the general public? Revisions needed: At a bare minimum, the rules should require that "produced water" be tested at two separate intervals across time for radioactivity. This is already required in Pennsylvania. The rules should also require that the requirements of the Illinois Low Level Radioactivity Waste Management Act be followed.

Sincerely, Brent Ritzel 810 N. Springer St. Carbondale, IL 62901

Revisions needed: At a bare minimum, the rules should require that "produced water" be tested at two separate intervals across time for radioactivity. This is already required in Pennsylvania. The rules should also require that the requirements of the Illinois Low Level Radioactivity Waste Management Act be followed.

Sincerely, Clara Kao Chicago, IL 60637

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Comment/Problem(s)/Needed Revisions: Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Notably absent from these proposed rules is a requirement for the testing of "produced water", the fluid that returns from the well during the later stage of production (after flowback). Under the proposed rules, "produced water" can be stored on site and/or can be "recycled", yet there is no testing requirement. Naturally occurring radioactive material (NORM) is found in "produced water" also. See Technologically enhanced naturally occurring radioactive materials in the oil industry (TENORM), Nukleonika 2009; 54(1):3-9, and sources cited therein, especially for TENORM in produced water in the U.S., available at [http://www.nukleonika.pl/www/back/full/vol54\\_2009/v54n1p003f.pdf](http://www.nukleonika.pl/www/back/full/vol54_2009/v54n1p003f.pdf). See also NORM is also found on scale in oil pipes and on fracking equipment. (See Kentucky Resources Council Proposes Comprehensive Plan For Investigating Radiological Contamination In Martha Oil Field. August 11, 2005. <http://www.kyrc.org/webnewspro/112381723236086.shtml>.) IDNR's definitions of "flowback water" and "produced water" are different. The two are distinguishably different enough that they are treated as separate types of fluid by both the Hydraulic Fracturing Regulatory Act and by the DNR Rules. Discharge of produced water onto the ground or into surface water or water drainage way is prohibited but it is not tested for radioactivity. This despite the fact that this fluid will be in contact with the naturally occurring radioactive elements in the ground for a longer period than the flowback and that it is much more likely to be radioactive. Problems: Failure to test produced water for radioactivity is problematic for a variety of reasons including: The health and safety of workers on the site who will be unaware of the levels of radioactivity they are being exposed to. The health and safety of workers transporting produced water who will also be in the dark regarding the levels of radioactivity they will be exposed to. The risk of storing radioactive material in tanks not created for storing radioactive materials. The risk of "recycling" produced water—radioactivity cannot be removed by recycling. The risk to the public in transporting radioactive materials Argonne National Laboratory recently cautioned about radiological doses: "It is commonly accepted that efforts should be undertaken at all times to keep radiological doses 'as low as reasonably achievable,' which is referred to as the ALARA principle or requirement." Overview of Radiological Dose and Risk Assessment (April 2011). DNR is failing to even adequately test for radioactivity and therefore, will not know the levels of radioactivity. How, then, can DNR adequately protect workers and the general public? Revisions needed: At a bare minimum, the rules should require that "produced water" be tested at two separate intervals across time for radioactivity. This is already required in Pennsylvania. The rules should also require that the requirements of the Illinois Low Level Radioactivity Waste Management Act be followed.

Discharge of produced water onto the ground or into surface water or water drainage way is prohibited but it is not tested for radioactivity. This despite the fact that this fluid will be in contact with the naturally occurring radioactive elements in the ground for a longer period than the flowback and that it is much more likely to be radioactive. Problems: Failure to test produced water for radioactivity is problematic for a variety of reasons including: The health and safety of workers on the site who will be unaware of the levels of radioactivity they are being exposed to. The health and safety of workers transporting produced water who will also be in the dark regarding the levels of radioactivity they will be exposed to. The risk of storing radioactive material in tanks not created for storing radioactive materials. The risk of "recycling" produced water—radioactivity cannot be removed by recycling. The risk to the public in transporting radioactive materials Argonne National Laboratory recently cautioned about radiological doses: "It is commonly accepted that efforts should be undertaken at all times to keep radiological doses 'as low as reasonably achievable,' which is referred to as the ALARA principle or requirement." Overview of Radiological Dose and Risk Assessment (April 2011). DNR is failing to even adequately test for radioactivity and therefore, will not know the levels of radioactivity. How, then, can DNR adequately protect workers and the general public? Revisions needed: At a bare minimum, the rules should require that "produced water" be tested at two separate intervals across time for radioactivity. This is already required in Pennsylvania. The rules should also require that the requirements of the Illinois Low Level Radioactivity Waste Management Act be followed.

Sincerely, Jan A Pietrzak 12031 S 72nd Ct Palos Heights, IL 60463

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Comment/Problem(s)/Needed Revisions: Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Notably absent from these proposed rules is a requirement for the testing of "produced water", the fluid that returns from the well during the later stage of production (after flowback). Under the proposed rules, "produced water" can be stored on site and/or can be "recycled", yet there is no testing requirement. Naturally occurring radioactive material (NORM) is found in "produced water" also. See Technologically enhanced naturally occurring radioactive materials in the oil industry (TENORM), Nukleonika 2009; 54(1):3-9, and sources cited therein, especially for TENORM in produced water in the U.S., available at [http://www.nukleonika.pl/www/back/full/vol54\\_2009/v54n1p003f.pdf](http://www.nukleonika.pl/www/back/full/vol54_2009/v54n1p003f.pdf). See also NORM is also found on scale in oil pipes and on fracking equipment. (See Kentucky Resources Council Proposes Comprehensive Plan For Investigating Radiological Contamination In Martha Oil Field. August 11, 2005. <http://www.kyrc.org/webnewspro/112381723236086.shtml>.) IDNR's definitions of "flowback water" and "produced water" are different. The two are distinguishably different enough that they are treated as separate types of fluid by both the Hydraulic Fracturing Regulatory Act and by the DNR Rules. Discharge of produced water onto the ground or into surface water or water drainage way is prohibited but it is not tested for radioactivity. This despite the fact that this fluid will be in contact with the naturally occurring radioactive elements in the ground for a longer period than the flowback and that it is much more likely to be radioactive. Problems: Failure to test produced water for radioactivity is problematic for a variety of reasons including: The health and safety of workers on the site who will be unaware of the levels of radioactivity they are being exposed to. Under the proposed rules, "produced water" can be stored on site and/or can be "recycled", yet there is no testing requirement. Naturally occurring radioactive material (NORM) is found in "produced water" also. See Technologically enhanced naturally occurring radioactive materials in the oil industry (TENORM), Nukleonika 2009; 54(1):3-9, and sources cited therein, especially for TENORM in produced water in the U.S., available at [http://www.nukleonika.pl/www/back/full/vol54\\_2009/v54n1p003f.pdf](http://www.nukleonika.pl/www/back/full/vol54_2009/v54n1p003f.pdf). See also NORM is also found on scale in oil pipes and on fracking equipment. (See Kentucky Resources Council Proposes Comprehensive Plan For Investigating Radiological Contamination In Martha Oil Field. August 11, 2005. <http://www.kyrc.org/webnewspro/112381723236086.shtml>.) IDNR's definitions of "flowback water" and "produced water" are different. The two are distinguishably different enough that they are treated as separate types of fluid by both the Hydraulic Fracturing Regulatory Act and by the DNR Rules. Discharge of produced water onto the ground or into surface water or water drainage way is prohibited but it is not tested for radioactivity. This despite the fact that this fluid will be in contact with the naturally occurring radioactive elements in the ground for a longer period than the flowback and that it is much more likely to be radioactive. Problems: Failure to test produced water for radioactivity is problematic for a variety of reasons including: The health and safety of workers on the site who will be unaware of the levels of radioactivity they are being exposed to. The health and safety of workers transporting produced water who will also be in the dark regarding the levels of radioactivity they will be exposed to. The risk of storing radioactive material in tanks not created for storing radioactive materials. The risk of "recycling" produced water—radioactivity cannot be removed by recycling. The risk to the public in transporting radioactive materials Argonne National Laboratory recently cautioned about radiological doses: "It is commonly accepted that efforts should be undertaken at all times to keep radiological doses 'as low as reasonably achievable,' which is referred to as the ALARA principle or requirement." Overview of Radiological Dose and Risk Assessment (April 2011). DNR is failing to even adequately test for radioactivity and therefore, will not know the levels of radioactivity. How, then, can DNR adequately protect workers and the general public? Revisions needed: At a bare minimum, the rules should require that "produced water" be tested at two separate intervals across time for radioactivity. This is already required in Pennsylvania. The rules should also require that the requirements of the Illinois Low Level Radioactivity Waste Management Act be followed.

Sincerely, Ken Buck Naperville, IL 60540

Revisions needed: At a bare minimum, the rules should require that "produced water" be tested at two separate intervals across time for radioactivity. This is already required in Pennsylvania. The rules should also require that the requirements of the Illinois Low Level Radioactivity Waste Management Act be followed.

Sincerely, M Smerken Murphysboro, IL 62966

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Comment/Problem(s)/Needed Revisions: Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Notably absent from these proposed rules is a requirement for the testing of "produced water", the fluid that returns from the well during the later stage of production (after flowback). Under the proposed rules, "produced water" can be stored on site and/or can be "recycled", yet there is no testing requirement. Naturally occurring radioactive material (NORM) is found in "produced water" also. See Technologically enhanced naturally occurring radioactive materials in the oil industry (TENORM), Nukleonika 2009; 54(1):3-9, and sources cited therein, especially for TENORM in produced water in the U.S., available at [http://www.nukleonika.pl/www/back/full/vol54\\_2009/v54n1p003f.pdf](http://www.nukleonika.pl/www/back/full/vol54_2009/v54n1p003f.pdf). See also NORM is also found on scale in oil pipes and on fracking equipment. (See Kentucky Resources Council Proposes Comprehensive Plan For Investigating Radiological Contamination In Martha Oil Field. August 11, 2005. <http://www.kyrc.org/webnewspro/112381723236086.shtml>.) IDNR's definitions of "flowback water" and "produced water" are different. The two are distinguishably different enough that they are treated as separate types of fluid by both the Hydraulic Fracturing Regulatory Act and by the DNR Rules. Discharge of produced water onto the ground or into surface water or water drainage way is prohibited but it is not tested for radioactivity. This despite the fact that this fluid will be in contact with the naturally occurring radioactive elements in the ground for a longer period than the flowback and that it is much more likely to be radioactive. Problems: Failure to test produced water for radioactivity is problematic for a variety of reasons including: The health and safety of workers on the site who will be unaware of the levels of radioactivity they are being exposed to. The health and safety of workers transporting produced water who will also be in the dark regarding the levels of radioactivity they will be exposed to. The risk of storing radioactive material in tanks not created for storing radioactive materials. The risk of "recycling" produced water—radioactivity cannot be removed by recycling. The risk to the public in transporting radioactive materials Argonne National Laboratory recently cautioned about radiological doses: "It is commonly accepted that efforts should be undertaken at all times to keep radiological doses 'as low as reasonably achievable,' which is referred to as the ALARA principle or requirement." Overview of Radiological Dose and Risk Assessment (April 2011). DNR is failing to even adequately test for radioactivity and therefore, will not know the levels of radioactivity. How, then, can DNR adequately protect workers and the general public? Revisions needed: At a bare minimum, the rules should require that "produced water" be tested at two separate intervals across time for radioactivity. This is already required in Pennsylvania. The rules should also require that the requirements of the Illinois Low Level Radioactivity Waste Management Act be followed.

Sincerely, Marissa Godlewski Carbondale, IL 62901

This despite the fact that this fluid will be in contact with the naturally occurring radioactive elements in the ground for a longer period than the flowback and that it is much more likely to be radioactive. Problems: Failure to test produced water for radioactivity is problematic for a variety of reasons including: The health and safety of workers on the site who will be unaware of the levels of radioactivity they are being exposed to. The health and safety of workers transporting produced water who will also be in the dark regarding the levels of radioactivity they will be exposed to. The risk of storing radioactive material in tanks not created for storing radioactive materials. The risk of "recycling" produced water—radioactivity cannot be removed by recycling. The risk to the public in transporting radioactive materials Argonne National Laboratory recently cautioned about radiological doses: "It is commonly accepted that efforts should be undertaken at all times to keep radiological doses 'as low as reasonably achievable,' which is referred to as the ALARA principle or requirement." Overview of Radiological Dose and Risk Assessment (April 2011). DNR is failing to even adequately test for radioactivity and therefore, will not know the levels of radioactivity. How, then, can DNR adequately protect workers and the general public? Revisions needed: At a bare minimum, the rules should require that "produced water" be tested at two separate intervals across time for radioactivity. This is already required in Pennsylvania. The rules should also require that the requirements of the Illinois Low Level Radioactivity Waste Management Act be followed.

Sincerely, Nancy Onderdonk 1456 W Granville Chicago, IL 60660

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Comment/Problem(s)/Needed Revisions: Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Notably absent from these proposed rules is a requirement for the testing of "produced water", the fluid that returns from the well during the later stage of production (after flowback). Under the proposed rules, "produced water" can be stored on site and/or can be "recycled", yet there is no testing requirement. This is irresponsible! Naturally occurring radioactive material (NORM) is found in "produced water" also. See Technologically enhanced naturally occurring radioactive materials in the oil industry (TENORM), Nukleonika 2009; 54(1):3-9, and sources cited therein, especially for TENORM in produced water in the U.S., available at [http://www.nukleonika.pl/www/back/full/vol54\\_2009/v54n1p003f.pdf](http://www.nukleonika.pl/www/back/full/vol54_2009/v54n1p003f.pdf). See also NORM is also found on scale in oil pipes and on fracking equipment. (See Kentucky Resources Council Proposes Comprehensive Plan For Investigating Radiological Contamination In Martha Oil Field. August 11, 2005. <http://www.kyrc.org/webnewspro/112381723236086.shtml>.) IDNR's definitions of "flowback water" and "produced water" are different. The two are distinguishably different enough that they are treated as separate types of fluid by both the Hydraulic Fracturing Regulatory Act and by the DNR Rules. Discharge of produced water onto the ground or into surface water or water drainage way is prohibited but it is not tested for radioactivity. This despite the fact that this fluid will be in contact with the naturally occurring radioactive elements in the ground for a longer period than the flowback and that it is much more likely to be radioactive. Problems: Failure to test produced water for radioactivity is problematic for a variety of reasons including: The health and safety of workers on the site who will be unaware of the levels of radioactivity they are being exposed to. The health and safety of workers transporting produced water who will also be in the dark regarding the levels of radioactivity they will be exposed to. See Technologically enhanced naturally occurring radioactive materials in the oil industry (TENORM), Nukleonika 2009; 54(1):3-9, and sources cited therein, especially for TENORM in produced water in the U.S., available at [http://www.nukleonika.pl/www/back/full/vol54\\_2009/v54n1p003f.pdf](http://www.nukleonika.pl/www/back/full/vol54_2009/v54n1p003f.pdf). See also NORM is also found on scale in oil pipes and on fracking equipment. (See Kentucky Resources Council Proposes Comprehensive Plan For Investigating Radiological Contamination In Martha Oil Field. August 11, 2005. <http://www.kyrc.org/webnewspro/112381723236086.shtml>.) IDNR's definitions of "flowback water" and "produced water" are different. The two are distinguishably different enough that they are treated as separate types of fluid by both the Hydraulic Fracturing Regulatory Act and by the DNR Rules. Discharge of produced water onto the ground or into surface water or water drainage way is prohibited but it is not tested for radioactivity. This despite the fact that this fluid will be in contact with the naturally occurring radioactive elements in the ground for a longer period than the flowback and that it is much more likely to be radioactive. Problems: Failure to test produced water for radioactivity is problematic for a variety of reasons including: The health and safety of workers on the site who will be unaware of the levels of radioactivity they are being exposed to. The health and safety of workers transporting produced water who will also be in the dark regarding the levels of radioactivity they will be exposed to. The risk of storing radioactive material in tanks not created for storing radioactive materials. The risk of "recycling" produced water—radioactivity cannot be removed by recycling. The risk to the public in transporting radioactive materials Argonne National Laboratory recently cautioned about radiological doses: "It is commonly accepted that efforts should be undertaken at all times to keep radiological doses 'as low as reasonably achievable,' which is referred to as the ALARA principle or requirement." Overview of Radiological Dose and Risk Assessment (April 2011). DNR is failing to even adequately test for radioactivity and therefore, will not know the levels of radioactivity. How, then, can DNR adequately protect workers and the general public? Revisions needed: At a bare minimum, the rules should require that "produced water" be tested at two separate intervals across time for radioactivity. This is already required in Pennsylvania. The rules should also require that the requirements of the Illinois Low Level Radioactivity Waste Management Act be followed.

Sincerely, Raymond D. Gayton 453 Tahoe Street Park Forest, IL 60466

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Comment/Problem(s)/Needed Revisions: Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Notably absent from these proposed rules is a requirement for the testing of "produced water", the fluid that returns from the well during the later stage of production (after flowback). Under the proposed rules, "produced water" can be stored on site and/or can be "recycled", yet there is no testing requirement. Naturally occurring radioactive material (NORM) is found in "produced water" also. See Technologically enhanced naturally occurring radioactive materials in the oil industry (TENORM), Nukleonika 2009; 54(1):3-9, and sources cited therein, especially for TENORM in produced water in the U.S., available at [http://www.nukleonika.pl/www/back/full/vol54\\_2009/v54n1p003f.pdf](http://www.nukleonika.pl/www/back/full/vol54_2009/v54n1p003f.pdf). See also NORM is also found on scale in oil pipes and on fracking equipment. (See Kentucky Resources Council Proposes Comprehensive Plan For Investigating Radiological Contamination In Martha Oil Field. August 11, 2005. <http://www.kyrc.org/webnewspro/112381723236086.shtml>.) IDNR's definitions of "flowback water" and "produced water" are different. The two are distinguishably different enough that they are treated as separate types of fluid by both the Hydraulic Fracturing Regulatory Act and by the DNR Rules. In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Comment/Problem(s)/Needed Revisions: Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Notably absent from these proposed rules is a requirement for the testing of "produced water", the fluid that returns from the well during the later stage of production (after flowback). Under the proposed rules, "produced water" can be stored on site and/or can be "recycled", yet there is no testing requirement. Naturally occurring radioactive material (NORM) is found in "produced water" also. See Technologically enhanced naturally occurring radioactive materials in the oil industry (TENORM), Nukleonika 2009; 54(1):3-9, and sources cited therein, especially for TENORM in produced water in the U.S., available at [http://www.nukleonika.pl/www/back/full/vol54\\_2009/v54n1p003f.pdf](http://www.nukleonika.pl/www/back/full/vol54_2009/v54n1p003f.pdf). See also NORM is also found on scale in oil pipes and on fracking equipment. (See Kentucky Resources Council Proposes Comprehensive Plan For Investigating Radiological Contamination In Martha Oil Field. August 11, 2005. <http://www.kyrc.org/webnewspro/112381723236086.shtml>.) IDNR's definitions of "flowback water" and "produced water" are different. The two are distinguishably different enough that they are treated as separate types of fluid by both the Hydraulic Fracturing Regulatory Act and by the DNR Rules. Discharge of produced water onto the ground or into surface water or water drainage way is prohibited but it is not tested for radioactivity. This despite the fact that this fluid will be in contact with the naturally occurring radioactive elements in the ground for a longer period than the flowback and that it is much more likely to be radioactive. Problems: Failure to test produced water for radioactivity is problematic for a variety of reasons including: The health and safety of workers on the site who will be unaware of the levels of radioactivity they are being exposed to. The health and safety of workers transporting produced water who will also be in the dark regarding the levels of radioactivity they will be exposed to. The risk of storing radioactive material in tanks not created for storing radioactive materials. The risk of "recycling" produced water—radioactivity cannot be removed by recycling. The risk to the public in transporting radioactive materials. Argonne National Laboratory recently cautioned about radiological doses: "It is commonly accepted that efforts should be undertaken at all times to keep radiological doses 'as low as reasonably achievable,' which is referred to as the ALARA principle or requirement." Overview of Radiological Dose and Risk Assessment (April 2011). DNR is failing to even adequately test for radioactivity and therefore, will not know the levels of radioactivity. How, then, can DNR adequately protect workers and the general public? Revisions needed: At a bare minimum, the rules should require that "produced water" be tested at two separate intervals across time for radioactivity. This is already required in Pennsylvania. The rules should also require that the requirements of the Illinois Low Level Radioactivity Waste Management Act be followed. **WE MUST HAVE TESTING REQUIREMENTS FOR BOTH "produced water" and "flowback water" - - we cannot have a true picture if we don't have the true results.**

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Fracking must be stopped at any cost. If it cannot be accomplished by law then it will be accomplished by other means. These are unlicensed criminals operating without oversight. They are poisoning the state long-term, lying about it, spinning it, killing and bribing their way to achieving their 'goal'. Poisoned water, disease and death. Fracking spells nothing else. Fracking is on course to destroy rural Illinois and poison it for hundreds of years to come. Anyone who goes there will suffer adverse health effects and die. Those in favor of fracking can volunteer to live right near a fracking site and drink poison, radioactive, flammable, cancer-causing water if they 'believe' in it so much. But those in favor of fracking would rather commit mass murder from a distance and go to the bank. A few hundred people will profit greatly from fracking and those are the only ones in favor of it.

Sincerely, Ellen Chicago, IL 60610

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Legal issues: Act §1-75(a)7 requires radioactivity testing "once per well site" for (1) flowback water and ground "adjacent to" (2) storage tanks and (3) reserve pits. . Act § 1-120 requires IDNR compliance with all "applicable federal, State, and local laws." One applicable State law is the Illinois Low-Level Radioactive Waste Management Act (PA 83-991 / 420ILCS20). Another is the Occupational Health and Safety Administration (OSHA) standards for workplace safety in settings with exposure to radioactivity (29 CFR 1910.1096). Rules §245.850(d)1-E and §245.850(e) are incomplete and deficient, and these inadequacies can "constitute a serious threat"--indeed, deadly threat-- "to the public interest, safety, or welfare" of Illinois citizens." Several problems stand out. 1.) IDNR does not define a fixed date ( $\pm X$  days). Day 1, Hour 1 test results will be orders of magnitude lower than either Day 2 or Day 10 tests results, and Day 10 tests results will be significantly lower than Day 80 ( $\pm 7$  days) results. Failure to specify a test date ( $\pm X$  days) renders test data meaningless and allows companies to report suppressed and meaningless results by reporting Day 1, < Hour 1 results. The figure below, provided by the USGS, illustrates the nature of the problem. Please note that radium is NOT tested at Day 1, < Hour 1. However, radium coprecipitates with barium, which is represented in total dissolved solids (TDS). It will therefore track TDS fairly closely. Second, there are two pits on a frack pad. Implications: According to studies by the Illinois State Geological Survey, the Illinois New Albany Shale Formation, the source rock for our oil and gas reserves, has above average levels of uranium (29 ppm) and generates oilfield brine. This uranium decays into radium and thence radon. Both uranium and radium are water soluble. Moreover, the U.S. Geological Survey has found oil field brine or produced water in Southern Illinois to have Radium226 levels that average more than 1,000 picoCuries per liter, which is 67 times above the maximum contamination level of the EPA. Radium226 has a half life of 1,600 years. Uranium228 has a half life of 4.468 billion years. The radioactive levels for produced water from shale gas operations are likely to be 2 to 4 times higher than oilfield brine -- on average, 2,000 to 4,000 piccoCuries per liter. Moreover, when produced water is removed along with hydrocarbons, excess radioactive salts in the water precipitate out and become scale on pipe or tanks or sludge in the bottom of tanks or pits. The levels of radioactivity can exceed 100,000 picoCuries per gram and constitute a hazard to workers, or others who are exposed to recycled scrap metal from gas and oil operations. This is why high levels of radioactivity have been found in school playground equipment and bleachers in school sports stadiums. Do we really want untested oil and gas field scrap metal sold into Illinois markets? The problems cited above are why Illinois, with its large number of nuclear power plants, has a Low-Level Radioactive Waste Management Act. It and OSHA are the applicable State and Federal Laws with respect to the issue of radioactive waste and work safety standards in settings with exposure to radioactivity. If we faithfully follow applicable state and federal laws, Illinois can minimize the pernicious problems other states are going to face from the uncontrolled release of radioactive elements into their water and soil and work

## Fair Economy Illinois

---

and non-work settings. We should prevent these problem from the start. Cleanup, after the oil and gas industry is gone, will be dreadfully expensive.

Sincerely, Kelvin Ho 736 W. 43rd St. (Apt. 3) Chicago, IL 60609

Not only should IDNR know that radioactive material occurs in Illinois oil and gas operations [see 62 Ill. Admin. Code secs. 240.860(e)(3), 240.861(k)(1)©], but they should also know that from the significant number of articles that have emerged over the years regarding radioactive material in water. In fact, hydraulic fracturing in the US, according to a recent report, produces enough toxic waste water in one year to flood Washington DC. (<http://www.theguardian.com/environment/2013/oct/04/fracking-us-toxic-waste-waterwashington>). Some of that wastewater is radioactive. In testing water up and downstream from a water treatment facility that treated fracturing waste, a recent Duke University study found elevated levels of "chloride and bromide, combined with strontium, radium, oxygen, and hydrogen isotopic compositions, are present in the Marcellus shale wastewaters." Moreover, the study found that "[r]adium levels in samples collected at the [water treatment] facility were 200 times greater than samples taken upstream. Such elevated levels of radioactivity are above regulated levels and would normally be seen at licensed radioactive disposal facilities, according to the scientists at Duke University's Nicholas School of the Environment in North Carolina." (<http://www.theguardian.com/environment/2013/oct/02/dangerous-radioactivity-frackingwaste-pennsylvania>) It is not a question of whether or not radioactive material is found in fracturing wastewater. It will be found. The IDNR rules must absolutely specify how plowback AND produced water should be treated if they test positive for radioactivity. The rules should also require that the Illinois Low Level Radioactivity Waste Management Act be followed.

Sincerely, Sara Buck Chicago , IL 60640

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Radioactive water is not an acceptable product of fracking, for communities or the environment. Produced water must be tested at two separate intervals across time for radioactivity, as is required in states such as Pennsylvania. Additionally, the rules must be revised so that the requirements for the Illinois Low Level Radioactivity Waste Management Act be followed. At the very least, produced water should not be recycled until it is proven beyond doubt that it does not contain naturally occurring radioactive material. If it does contain naturally occurring radioactive material, it should not be transported due to public health risks. If the water cannot be safely recycled, stored, or transported, then fracking must cease in that location (or never be implemented in the first place). This would not make the rules unduly restrictive, but rather comprehensive and useful--capable of regulating a dangerous and poorly documented fossil fuel extraction process.

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Radioactive water is not an acceptable product of fracking, for communities or the environment. Produced water must be tested at two separate intervals across time for radioactivity, as is required in states such as Pennsylvania. Additionally, the rules must be revised so that the requirements for the Illinois Low Level Radioactivity Waste Management Act be followed. At the very least, produced water should not be recycled until it is proven beyond doubt that it does not contain naturally occurring radioactive material. If it does contain naturally occurring radioactive material, it should not be transported due to public health risks. If the water cannot be safely recycled, stored, or transported, then fracking must cease in that location (or never be implemented in the first place). This would not make the rules unduly restrictive, but rather comprehensive and useful--capable of regulating a dangerous and poorly documented fossil fuel extraction process.

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Radioactivity in fracking operations: More loopholes How does this affect me: Radioactivity Relevant parts of the Proposed Administrative Rules: 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req. Subsection (d)(1) of Section 245.850 provides for testing radioactivity only one time— during the early flowback stage—and only for "naturally occurring radioactive materials". The problems with this are identified below. Problems: The proposed rules do not include any standards or protocols to follow if testing of flowback water shows unacceptable levels of radioactivity. The proposed rules do not require the testing of "produced water", which is the water produced from a well in conjunction with oil or natural gas production. This is where radioactivity is most likely to show up. It should be noted that while these Rules have been purported to be the strongest in the nation, PA law requires the testing of produced water at two separate intervals. The proposed rules do not require testing for added radioactive materials, like depleted uranium, which can be used in the perforation/fracturing operation. The proposed rules do not test work areas for levels of radioactivity that would call for OSHA standards of occupational safety. These deficiencies, cumulatively or singly, would pose a significant risk to the public health and safety, property, aquatic life, and wildlife, in violation of section 1-75(a) (2) of the Hydraulic Fracturing Regulatory Act.

Sincerely, Sabrina Helen Bennett Hardenbergh 1 Hardenbergh Road Carbondale, IL 62902

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Radioactivity in fracking operations: Produced Water Needs to Be Tested for Radioactivity How does this affect me: Radioactivity Relevant parts of the Proposed Administrative Rules: 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Comment/Problem(s)/Needed Revisions: Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Notably absent from these proposed rules is a requirement for the testing of "produced water", the fluid that returns from the well during the later stage of production (after flowback). Under the proposed rules, "produced water" can be stored on site and/or can be "recycled", yet there is no testing requirement. Naturally occurring radioactive material (NORM) is found in "produced water" also. See Technologically enhanced naturally occurring radioactive materials in the oil industry (TENORM), Nukleonika 2009; 54(1):3-9, and sources cited therein, especially for TENORM in produced water in the U.S., available at

[http://www.nukleonika.pl/www/back/full/vol54\\_2009/v54n1p003f.pdf](http://www.nukleonika.pl/www/back/full/vol54_2009/v54n1p003f.pdf). See also NORM is also found on scale in oil pipes and on fracking equipment. (See Kentucky Resources Council Proposes Comprehensive Plan For Investigating Radiological Contamination In Martha Oil Field. August 11, 2005.

<http://www.kyrc.org/webnewspro/112381723236086.shtml>.) IDNR's definitions of "flowback water" and "produced water" are different. The two are distinguishably different enough that they are treated as separate types of fluid by both the Hydraulic Fracturing Regulatory Act and by the DNR Rules.

Discharge of produced water onto the ground or into surface water or water drainage way is prohibited but it is not tested for radioactivity. This despite the fact that this fluid will be in contact with the naturally occurring radioactive elements in the ground for a longer period than the flowback and that it is much more likely to be radioactive. Problems: Failure to test produced water for radioactivity is problematic for a variety of reasons including: The health and safety of workers on the site who will be unaware of the levels of radioactivity they are being exposed to. The health and safety of workers transporting produced water who will also be in the dark regarding the levels of radioactivity they will be exposed to. The risk of storing radioactive material in tanks not created for storing radioactive materials. The risk of "recycling" produced water—radioactivity cannot be removed by recycling. The risk to the public in transporting radioactive materials Argonne National Laboratory recently cautioned about radiological doses: "It is commonly accepted that efforts should be undertaken at all times to keep radiological doses 'as low as reasonably achievable,' which is referred to as the ALARA principle or requirement." Overview of Radiological Dose and Risk Assessment (April 2011). DNR is failing to even adequately test for radioactivity and therefore, will not know the levels of radioactivity. How, then, can DNR adequately protect workers and the general public? Revisions needed: At a bare minimum, the rules should require that "produced water" be tested at two separate intervals across time for

## Fair Economy Illinois

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Relevant parts of the Proposed Administrative Rules: 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req. . Section 1-75 of the Hydraulic Fracturing Regulator Act mandates that “excess hydraulic fracturing flowback captured for temporary storage in a reserve pit as provided in paragraph (2) of this subsection must be removed from the well site within 7 days.” But Section 245.850 of the proposed rules states, “Any excess hydraulic fracturing flowback captured for temporary storage in a reserve pit as provided in Section 245.825 must be removed from the well site or transferred to storage in above-ground tanks for later disposal or recycling within 7 days after completion of high volume horizontal hydraulic fracturing operations.” Problem: The amendment of “after completion of high volume horizontal hydraulic fracturing operations” opens the door for the potential abuse of emergency pits. Storage in closed tanks can be costly for the industry. An unscrupulous operator wanting to cut costs could simply claim that there was more flowback than expected and end up using open pits for storage for the duration of the fracking process. The clear intent of the statute is to ensure that wastewater is stored in tanks except in the emergency event of an unforeseeable overflow, in which case it is preferable that the overflow go to a pit than simply spill on the ground. But in such event, the overflow is expressly required in the statute to be removed within a week. Through omission and misinterpretation, the regulations are not implementing this statutory directive. Section 245.210(a)(11), requires that an applicant submit a Hydraulic Fracturing Fluids and Flowback Plan. The plan does not include requirements to ensure that tank capacity is accurately calculated. Without such method, there is nothing in the regulations to prevent operators from underestimating the size of the tanks they need, so as to make routine use of the reserve pit for the resulting overflows. Operators presumably have an economic incentive to do so in order to hold down the cost of tank storage. Compounding this incentive is the Department’s weakening of the statutory directive that fluids deposited in a reserve pit be removed within 7 days (Section 1-75(c)(5)). The regulations fail to require such prompt removal, allowing, at subsection 245.850(c), the overflow to remain in the reserve pits until 7 days “after completion of high volume horizontal hydraulic fracturing operations.” Certainly on a multi-well pad, hydraulic fracturing operations can continue for a month or more, meaning that the flowback fluid could be left sitting in the reserve pit, creating environmental risk, for much longer than a week. Revisions needed: First, require that drillers anticipate appropriate sized tanks for sufficient storage of flowback and produced water by establishing a method for tank capacity calculation. Second, clarify that wastewater must be removed from the pit within 7 days of the event that triggered the use of the pit rather than 7 days after fracking operations are complete, in accordance with the law.

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Section 1-75 of the Hydraulic Fracturing Regulator Act mandates that “excess hydraulic fracturing flowback captured for temporary storage in a reserve pit as provided in paragraph (2) of this subsection must be removed from the well site within 7 days.” But Section 245.850 of the proposed rules states, “Any excess hydraulic fracturing flowback captured for temporary storage in a reserve pit as provided in Section 245.825 must be removed from the well site or transferred to storage in above-ground tanks for later disposal or recycling within 7 days after completion of high volume horizontal hydraulic fracturing operations.” Problem: The amendment of “after completion of high volume horizontal hydraulic fracturing operations” opens the door for the potential abuse of emergency pits. Storage in closed tanks can be costly for the industry. An unscrupulous operator wanting to cut costs could simply claim that there was more flowback than expected and end up using open pits for storage for the duration of the fracking process. The clear intent of the statute is to ensure that wastewater is stored in tanks except in the emergency event of an unforeseeable overflow, in which case it is preferable that the overflow go to a pit than simply spill on the ground. But in such event, the overflow is expressly required in the statute to be removed within a week. Through omission and misinterpretation, the regulations are not implementing this statutory directive. Section 245.210(a)(11), requires that an applicant submit a Hydraulic Fracturing Fluids and Flowback Plan. The plan does not include requirements to ensure that tank capacity is accurately calculated. Without such method, there is nothing in the regulations to prevent operators from underestimating the size of the tanks they need, so as to make routine use of the reserve pit for the resulting overflows. Operators presumably have an economic incentive to do so in order to hold down the cost of tank storage. Compounding this incentive is the Department’s weakening of the statutory directive that fluids deposited in a reserve pit be removed within 7 days (Section 1-75(c)(5)). The regulations fail to require such prompt removal, allowing, at subsection 245.850(c), the overflow to remain in the reserve pits until 7 days “after completion of high volume horizontal hydraulic fracturing operations.” Certainly on a multi-well pad, hydraulic fracturing operations can continue for a month or more, meaning that the flowback fluid could be left sitting in the reserve pit, creating environmental risk, for much longer than a week. Revisions needed: First, require that drillers anticipate appropriate sized tanks for sufficient storage of flowback and produced water by establishing a method for tank capacity calculation. Second, clarify that wastewater must be removed from the pit within 7 days of the event that triggered the use of the pit rather than 7 days after fracking operations are complete, in accordance with the law.

Sincerely, Abraham Secular Chicago, IL 60615

Operators presumably have an economic incentive to do so in order to hold down the cost of tank storage. Compounding this incentive is the Department’s weakening of the statutory directive that fluids deposited in a reserve pit be removed within 7 days (Section 1-75(c)(5)). The regulations fail to require such prompt removal, allowing, at subsection 245.850(c), the overflow to remain in the reserve pits until 7 days “after completion of high volume horizontal hydraulic fracturing operations.” Certainly on a multi-well pad, hydraulic fracturing operations can continue for a month or more, meaning that the flowback fluid could be left sitting in the reserve pit, creating environmental risk, for much longer than a week. Revisions needed: First, require that drillers anticipate appropriate sized tanks for sufficient storage of flowback and produced water by establishing a method for tank capacity calculation. Second, clarify that wastewater must be removed from the pit within 7 days of the event that triggered the use of the pit rather than 7 days after fracking operations are complete, in accordance with the law.

Sincerely, Angela Li Chicago, IL 60637

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Section 1-75 of the Hydraulic Fracturing Regulator Act mandates that “excess hydraulic fracturing flowback captured for temporary storage in a reserve pit as provided in paragraph (2) of this subsection must be removed from the well site within 7 days.” But Section 245.850 of the proposed rules states, “Any excess hydraulic fracturing flowback captured for temporary storage in a reserve pit as provided in Section 245.825 must be removed from the well site or transferred to storage in above-ground tanks for later disposal or recycling within 7 days after completion of high volume horizontal hydraulic fracturing operations.” Problem: The amendment of “after completion of high volume horizontal hydraulic fracturing operations” opens the door for the potential abuse of emergency pits. Storage in closed tanks can be costly for the industry. An unscrupulous operator wanting to cut costs could simply claim that there was more flowback than expected and end up using open pits for storage for the duration of the fracking process. The clear intent of the statute is to ensure that wastewater is stored in tanks except in the emergency event of an unforeseeable overflow, in which case it is preferable that the overflow go to a pit than simply spill on the ground. But in such event, the overflow is expressly required in the statute to be removed within a week. Through omission and misinterpretation, the regulations are not implementing this statutory directive. Section 245.210(a)(11), requires that an applicant submit a Hydraulic Fracturing Fluids and Flowback Plan. The plan does not include requirements to ensure that tank capacity is accurately calculated. Without such method, there is nothing in the regulations to prevent operators from underestimating the size of the tanks they need, so as to make routine use of the reserve pit for the resulting overflows. Operators presumably have an economic incentive to do so in order to hold down the cost of tank storage. Compounding this incentive is the Department’s weakening of the statutory directive that fluids deposited in a reserve pit be removed within 7 days (Section 1-75(c)(5)). The regulations fail to require such prompt removal, allowing, at subsection 245.850(c), the overflow to remain in the reserve pits until 7 days “after completion of high volume horizontal hydraulic fracturing operations.” Certainly on a multi-well pad, hydraulic fracturing operations can continue for a month or more, meaning that the flowback fluid could be left sitting in the reserve pit, creating environmental risk, for much longer than a week. An unscrupulous operator wanting to cut costs could simply claim that there was more flowback than expected and end up using open pits for storage for the duration of the fracking process. The clear intent of the statute is to ensure that wastewater is stored in tanks except in the emergency event of an unforeseeable overflow, in which case it is preferable that the overflow go to a pit than simply spill on the ground. But in such event, the overflow is expressly required in the statute to be removed within a week. Through omission and misinterpretation, the regulations are not implementing this statutory directive. Section 245.210(a)(11), requires that an applicant submit a Hydraulic Fracturing Fluids and Flowback Plan. The plan does not include requirements to ensure that tank capacity is accurately calculated. Without such method, there is nothing in the regulations to prevent operators from underestimating the size of the tanks they need, so as to make routine use of the reserve pit for the resulting overflows. Operators presumably have an economic incentive to do so in order to hold down the cost of tank storage. Compounding this incentive is the Department’s weakening of the statutory directive that fluids deposited in a reserve pit be removed within 7 days (Section 1-75(c)(5)). The regulations fail to require such prompt removal, allowing, at subsection 245.850(c), the overflow to remain in the reserve pits until 7 days “after completion of high volume horizontal hydraulic fracturing operations.” Certainly on a multi-well pad, hydraulic fracturing operations can continue for a month or more, meaning that the flowback fluid could be left sitting in the reserve pit, creating environmental risk, for much longer than a week. Revisions needed: First, require that drillers anticipate appropriate sized tanks for sufficient storage of flowback and produced water by establishing a method for tank capacity calculation. Second, clarify that wastewater must be removed from the pit within 7 days of the event that triggered the use of the pit rather than 7 days after fracking operations are complete, in accordance with the law.

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Section 1-75 of the Hydraulic Fracturing Regulator Act mandates that “excess hydraulic fracturing flowback captured for temporary storage in a reserve pit as provided in paragraph (2) of this subsection must be removed from the well site within 7 days.” But Section 245.850 of the proposed rules states, “Any excess hydraulic fracturing flowback captured for temporary storage in a reserve pit as provided in Section 245.825 must be removed from the well site or transferred to storage in above-ground tanks for later disposal or recycling within 7 days after completion of high volume horizontal hydraulic fracturing operations.” Problem: The amendment of “after completion of high volume horizontal hydraulic fracturing operations” opens the door for the potential abuse of emergency pits. Storage in closed tanks can be costly for the industry. An unscrupulous operator wanting to cut costs could simply claim that there was more flowback than expected and end up using open pits for storage for the duration of the fracking process. The clear intent of the statute is to ensure that wastewater is stored in tanks except in the emergency event of an unforeseeable overflow, in which case it is preferable that the overflow go to a pit than simply spill on the ground. But in such event, the overflow is expressly required in the statute to be removed within a week. In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Section 1-75 of the Hydraulic Fracturing Regulator Act mandates that “excess hydraulic fracturing flowback captured for temporary storage in a reserve pit as provided in paragraph (2) of this subsection must be removed from the well site within 7 days.” But Section 245.850 of the proposed rules states, “Any excess hydraulic fracturing flowback captured for temporary storage in a reserve pit as provided in Section 245.825 must be removed from the well site or transferred to storage in above-ground tanks for later disposal or recycling within 7 days after completion of high volume horizontal hydraulic fracturing operations.” Problem: The amendment of “after completion of high volume horizontal hydraulic fracturing operations” opens the door for the potential abuse of emergency pits. Storage in closed tanks can be costly for the industry. An unscrupulous operator wanting to cut costs could simply claim that there was more flowback than expected and end up using open pits for storage for the duration of the fracking process. The clear intent of the statute is to ensure that wastewater is stored in tanks except in the emergency event of an unforeseeable overflow, in which case it is preferable that the overflow go to a pit than simply spill on the ground. But in such event, the overflow is expressly required in the statute to be removed within a week. Through omission and misinterpretation, the regulations are not implementing this statutory directive. Section 245.210(a)(11), requires that an applicant submit a Hydraulic Fracturing Fluids and Flowback Plan. The plan does not include requirements to ensure that tank capacity is accurately calculated. Without such method, there is nothing in the regulations to prevent operators from underestimating the size of the tanks they need, so as to make routine use of the reserve pit for the resulting overflows. Operators presumably have an economic incentive to do so in order to hold down the cost of tank storage. Compounding this incentive is the Department’s weakening of the statutory directive that fluids deposited in a reserve pit be removed within 7 days (Section 1-75(c)(5)). The regulations fail to require such prompt removal, allowing, at subsection 245.850(c), the overflow to remain in the reserve pits until 7 days “after completion of high volume horizontal hydraulic fracturing operations.” Certainly on a multi-well pad, hydraulic fracturing operations can continue for a month or more, meaning that the flowback fluid could be left sitting in the reserve pit, creating environmental risk, for much longer than a week. Revisions needed: First, require that drillers anticipate appropriate sized tanks for sufficient storage of flowback and produced water by establishing a method for tank capacity calculation. Second, clarify that wastewater must be removed from the pit within 7 days of the event that triggered the use of the pit rather than 7 days after fracking operations are complete, in accordance with the law.

Without such method, there is nothing in the regulations to prevent operators from underestimating the size of the tanks they need, so as to make routine use of the reserve pit for the resulting overflows. Operators presumably have an economic incentive to do so in order to hold down the cost of tank storage. Compounding this incentive is the Department’s weakening of the statutory directive that fluids deposited in a reserve pit be removed within 7 days (Section 1-75(c)(5)). The regulations fail to require such prompt removal, allowing, at subsection 245.850(c), the overflow to remain in the reserve pits until 7 days “after completion of high volume horizontal hydraulic fracturing operations.” Certainly on a multi-well pad, hydraulic fracturing operations can continue for a month or more, meaning that the flowback fluid could be left sitting in the reserve pit, creating environmental risk, for much longer than a week. Revisions needed: First, require that drillers anticipate appropriate sized tanks for sufficient storage of flowback and produced water by establishing a method for tank capacity calculation. Second, clarify that wastewater must be removed from the pit within 7 days of the event that triggered the use of the pit rather than 7 days after fracking operations are complete, in accordance with the law.

Sincerely, Curtis Morris Chicago, IL 60607

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Section 1-75 of the Hydraulic Fracturing Regulator Act mandates that “excess hydraulic fracturing flowback captured for temporary storage in a reserve pit as provided in paragraph (2) of this subsection must be removed from the well site within 7 days.” But Section 245.850 of the proposed rules states, “Any excess hydraulic fracturing flowback captured for temporary storage in a reserve pit as provided in Section 245.825 must be removed from the well site or transferred to storage in above-ground tanks for later disposal or recycling within 7 days after completion of high volume horizontal hydraulic fracturing operations.” Problem: The amendment of “after completion of high volume horizontal hydraulic fracturing operations” opens the door for the potential abuse of emergency pits. Storage in closed tanks can be costly for the industry. An unscrupulous operator wanting to cut costs could simply claim that there was more flowback than expected and end up using open pits for storage for the duration of the fracking process. The clear intent of the statute is to ensure that wastewater is stored in tanks except in the emergency event of an unforeseeable overflow, in which case it is preferable that the overflow go to a pit than simply spill on the ground. But in such event, the overflow is expressly required in the statute to be removed within a week. Through omission and misinterpretation, the regulations are not implementing this statutory directive. Section 245.210(a)(11), requires that an applicant submit a Hydraulic Fracturing Fluids and Flowback Plan. The plan does not include requirements to ensure that tank capacity is accurately calculated. Without such method, there is nothing in the regulations to prevent operators from underestimating the size of the tanks they need, so as to make routine use of the reserve pit for the resulting overflows. Operators presumably have an economic incentive to do so in order to hold down the cost of tank storage. Compounding this incentive is the Department’s weakening of the statutory directive that fluids deposited in a reserve pit be removed within 7 days (Section 1-75(c)(5)). The regulations fail to require such prompt removal, allowing, at subsection 245.850(c), the overflow to remain in the reserve pits until 7 days “after completion of high volume horizontal hydraulic fracturing operations.” Certainly on a multi-well pad, hydraulic fracturing operations can continue for a month or more, meaning that the flowback fluid could be left sitting in the reserve pit, creating environmental risk, for much longer than a week. An unscrupulous operator wanting to cut costs could simply claim that there was more flowback than expected and end up using open pits for storage for the duration of the fracking process. The clear intent of the statute is to ensure that wastewater is stored in tanks except in the emergency event of an unforeseeable overflow, in which case it is preferable that the overflow go to a pit than simply spill on the ground. But in such event, the overflow is expressly required in the statute to be removed within a week. Through omission and misinterpretation, the regulations are not implementing this statutory directive. Section 245.210(a)(11), requires that an applicant submit a Hydraulic Fracturing Fluids and Flowback Plan. The plan does not include requirements to ensure that tank capacity is accurately calculated. Without such method, there is nothing in the regulations to prevent operators from underestimating the size of the tanks they need, so as to make routine use of the reserve pit for the resulting overflows. Operators presumably have an economic incentive to do so in order to hold down the cost of tank storage. Compounding this incentive is the Department’s weakening of the statutory directive that fluids deposited in a reserve pit be removed within 7 days (Section 1-75(c)(5)). The regulations fail to require such prompt removal, allowing, at subsection 245.850(c), the overflow to remain in the reserve pits until 7 days “after completion of high volume horizontal hydraulic fracturing operations.” Certainly on a multi-well pad, hydraulic fracturing operations can continue for a month or more, meaning that the flowback fluid could be left sitting in the reserve pit, creating environmental risk, for much longer than a week. Revisions needed: First, require that drillers anticipate appropriate sized tanks for sufficient storage of flowback and produced water by establishing a method for tank capacity calculation. Second, clarify that wastewater must be removed from the pit within 7 days of the event that triggered the use of the pit rather than 7 days after fracking operations are complete, in accordance with the law.

Sincerely, Elizabeth A. Cerny 7728 Williams St. Downers Grove, IL 60516

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Section 1-75 of the Hydraulic Fracturing Regulator Act mandates that “excess hydraulic fracturing flowback captured for temporary storage in a reserve pit as provided in paragraph (2) of this subsection must be removed from the well site within 7 days.” But Section 245.850 of the proposed rules states, “Any excess hydraulic fracturing flowback captured for temporary storage in a reserve pit as provided in Section 245.825 must be removed from the well site or transferred to storage in above-ground tanks for later disposal or recycling within 7 days after completion of high volume horizontal hydraulic fracturing operations.” Problem: The amendment of “after completion of high volume horizontal hydraulic fracturing operations” opens the door for the potential abuse of emergency pits. Storage in closed tanks can be costly for the industry. An unscrupulous operator wanting to cut costs could simply claim that there was more flowback than expected and end up using open pits for storage for the duration of the fracking process. The clear intent of the statute is to ensure that wastewater is stored in tanks except in the emergency event of an unforeseeable overflow, in which case it is preferable that the overflow go to a pit than simply spill on the ground. But in such event, the overflow is expressly required in the statute to be removed within a week. Through omission and misinterpretation, the regulations are not implementing this statutory directive. In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Section 1-75 of the Hydraulic Fracturing Regulator Act mandates that “excess hydraulic fracturing flowback captured for temporary storage in a reserve pit as provided in paragraph (2) of this subsection must be removed from the well site within 7 days.” But Section 245.850 of the proposed rules states, “Any excess hydraulic fracturing flowback captured for temporary storage in a reserve pit as provided in Section 245.825 must be removed from the well site or transferred to storage in above-ground tanks for later disposal or recycling within 7 days after completion of high volume horizontal hydraulic fracturing operations.” Problem: The amendment of “after completion of high volume horizontal hydraulic fracturing operations” opens the door for the potential abuse of emergency pits. Storage in closed tanks can be costly for the industry. An unscrupulous operator wanting to cut costs could simply claim that there was more flowback than expected and end up using open pits for storage for the duration of the fracking process. The clear intent of the statute is to ensure that wastewater is stored in tanks except in the emergency event of an unforeseeable overflow, in which case it is preferable that the overflow go to a pit than simply spill on the ground. But in such event, the overflow is expressly required in the statute to be removed within a week. Through omission and misinterpretation, the regulations are not implementing this statutory directive. Section 245.210(a)(11), requires that an applicant submit a Hydraulic Fracturing Fluids and Flowback Plan. The plan does not include requirements to ensure that tank capacity is accurately calculated. Without such method, there is nothing in the regulations to prevent operators from underestimating the size of the tanks they need, so as to make routine use of the reserve pit for the resulting overflows. Operators presumably have an economic incentive to do so in order to hold down the cost of tank storage. Compounding this incentive is the Department’s weakening of the statutory directive that fluids deposited in a reserve pit be removed within 7 days (Section 1-75(c)(5)). The regulations fail to require such prompt removal, allowing, at subsection 245.850(c), the overflow to remain in the reserve pits until 7 days “after completion of high volume horizontal hydraulic fracturing operations.” Certainly on a multi-well pad, hydraulic fracturing operations can continue for a month or more, meaning that the flowback fluid could be left sitting in the reserve pit, creating environmental risk, for much longer than a week. Revisions needed: First, require that drillers anticipate appropriate sized tanks for sufficient storage of flowback and produced water by establishing a method for tank capacity calculation. Second, clarify that wastewater must be removed from the pit within 7 days of the event that triggered the use of the pit rather than 7 days after fracking operations are complete, in accordance with the law.

Sincerely, Girwana Baker Chicago, IL 60605

Without such method, there is nothing in the regulations to prevent operators from underestimating the size of the tanks they need, so as to make routine use of the reserve pit for the resulting overflows. Operators presumably have an economic incentive to do so in order to hold down the cost of tank storage. Compounding this incentive is the Department’s weakening of the statutory directive that fluids deposited in a reserve pit be removed within 7 days (Section 1-75(c)(5)). The regulations fail to require such prompt removal, allowing, at subsection 245.850(c), the overflow to remain in the reserve pits until 7 days “after completion of high volume horizontal hydraulic fracturing operations.” Certainly on a multi-well pad, hydraulic fracturing operations can continue for a month or more, meaning that the flowback fluid could be left sitting in the reserve pit, creating environmental risk, for much longer than a week. Revisions needed: First, require that drillers anticipate appropriate sized tanks for sufficient storage of flowback and produced water by establishing a method for tank capacity calculation. Second, clarify that wastewater must be removed from the pit within 7 days of the event that triggered the use of the pit rather than 7 days after fracking operations are complete, in accordance with the law.

Sincerely, Jason Busser Dixon, IL 61021

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Section 1-75 of the Hydraulic Fracturing Regulator Act mandates that “excess hydraulic fracturing flowback captured for temporary storage in a reserve pit as provided in paragraph (2) of this subsection must be removed from the well site within 7 days.” But Section 245.850 of the proposed rules states, “Any excess hydraulic fracturing flowback captured for temporary storage in a reserve pit as provided in Section 245.825 must be removed from the well site or transferred to storage in above-ground tanks for later disposal or recycling within 7 days after completion of high volume horizontal hydraulic fracturing operations.” Problem: The amendment of “after completion of high volume horizontal hydraulic fracturing operations” opens the door for the potential abuse of emergency pits. Storage in closed tanks can be costly for the industry. An unscrupulous operator wanting to cut costs could simply claim that there was more flowback than expected and end up using open pits for storage for the duration of the fracking process. The clear intent of the statute is to ensure that wastewater is stored in tanks except in the emergency event of an unforeseeable overflow, in which case it is preferable that the overflow go to a pit than simply spill on the ground. But in such event, the overflow is expressly required in the statute to be removed within a week. Through omission and misinterpretation, the regulations are not implementing this statutory directive. Section 245.210(a)(11), requires that an applicant submit a Hydraulic Fracturing Fluids and Flowback Plan. The plan does not include requirements to ensure that tank capacity is accurately calculated. Without such method, there is nothing in the regulations to prevent operators from underestimating the size of the tanks they need, so as to make routine use of the reserve pit for the resulting overflows. Operators presumably have an economic incentive to do so in order to hold down the cost of tank storage. Compounding this incentive is the Department’s weakening of the statutory directive that fluids deposited in a reserve pit be removed within 7 days (Section 1-75(c)(5)). The regulations fail to require such prompt removal, allowing, at subsection 245.850(c), the overflow to remain in the reserve pits until 7 days “after completion of high volume horizontal hydraulic fracturing operations.” Certainly on a multi-well pad, hydraulic fracturing operations can continue for a month or more, meaning that the flowback fluid could be left sitting in the reserve pit, creating environmental risk, for much longer than a week. Storage in closed tanks can be costly for the industry. An unscrupulous operator wanting to cut costs could simply claim that there was more flowback than expected and end up using open pits for storage for the duration of the fracking process. The clear intent of the statute is to ensure that wastewater is stored in tanks except in the emergency event of an unforeseeable overflow, in which case it is preferable that the overflow go to a pit than simply spill on the ground. But in such event, the overflow is expressly required in the statute to be removed within a week. Through omission and misinterpretation, the regulations are not implementing this statutory directive. Section 245.210(a)(11), requires that an applicant submit a Hydraulic Fracturing Fluids and Flowback Plan. The plan does not include requirements to ensure that tank capacity is accurately calculated. Without such method, there is nothing in the regulations to prevent operators from underestimating the size of the tanks they need, so as to make routine use of the reserve pit for the resulting overflows. Operators presumably have an economic incentive to do so in order to hold down the cost of tank storage. Compounding this incentive is the Department’s weakening of the statutory directive that fluids deposited in a reserve pit be removed within 7 days (Section 1-75(c)(5)). The regulations fail to require such prompt removal, allowing, at subsection 245.850(c), the overflow to remain in the reserve pits until 7 days “after completion of high volume horizontal hydraulic fracturing operations.” Certainly on a multi-well pad, hydraulic fracturing operations can continue for a month or more, meaning that the flowback fluid could be left sitting in the reserve pit, creating environmental risk, for much longer than a week. Revisions needed: First, require that drillers anticipate appropriate sized tanks for sufficient storage of flowback and produced water by establishing a method for tank capacity calculation. Second, clarify that wastewater must be removed from the pit within 7 days of the event that triggered the use of the pit rather than 7 days after fracking operations are complete, in accordance with the law.

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Section 1-75 of the Hydraulic Fracturing Regulator Act mandates that “excess hydraulic fracturing flowback captured for temporary storage in a reserve pit as provided in paragraph (2) of this subsection must be removed from the well site within 7 days.” But Section 245.850 of the proposed rules states, “Any excess hydraulic fracturing flowback captured for temporary storage in a reserve pit as provided in Section 245.825 must be removed from the well site or transferred to storage in above-ground tanks for later disposal or recycling within 7 days after completion of high volume horizontal hydraulic fracturing operations.” Problem: The amendment of “after completion of high volume horizontal hydraulic fracturing operations” opens the door for the potential abuse of emergency pits. Storage in closed tanks can be costly for the industry. An unscrupulous operator wanting to cut costs could simply claim that there was more flowback than expected and end up using open pits for storage for the duration of the fracking process. The clear intent of the statute is to ensure that wastewater is stored in tanks except in the emergency event of an unforeseeable overflow, in which case it is preferable that the overflow go to a pit than simply spill on the ground. In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Section 1-75 of the Hydraulic Fracturing Regulator Act mandates that “excess hydraulic fracturing flowback captured for temporary storage in a reserve pit as provided in paragraph (2) of this subsection must be removed from the well site within 7 days.” But Section 245.850 of the proposed rules states, “Any excess hydraulic fracturing flowback captured for temporary storage in a reserve pit as provided in Section 245.825 must be removed from the well site or transferred to storage in above-ground tanks for later disposal or recycling within 7 days after completion of high volume horizontal hydraulic fracturing operations.” Problem: The amendment of “after completion of high volume horizontal hydraulic fracturing operations” opens the door for the potential abuse of emergency pits. Storage in closed tanks can be costly for the industry. An unscrupulous operator wanting to cut costs could simply claim that there was more flowback than expected and end up using open pits for storage for the duration of the fracking process. The clear intent of the statute is to ensure that wastewater is stored in tanks except in the emergency event of an unforeseeable overflow, in which case it is preferable that the overflow go to a pit than simply spill on the ground. But in such event, the overflow is expressly required in the statute to be removed within a week. Through omission and misinterpretation, the regulations are not implementing this statutory directive. Section 245.210(a)(11), requires that an applicant submit a Hydraulic Fracturing Fluids and Flowback Plan. The plan does not include requirements to ensure that tank capacity is accurately calculated. Without such method, there is nothing in the regulations to prevent operators from underestimating the size of the tanks they need, so as to make routine use of the reserve pit for the resulting overflows. Operators presumably have an economic incentive to do so in order to hold down the cost of tank storage. Compounding this incentive is the Department’s weakening of the statutory directive that fluids deposited in a reserve pit be removed within 7 days (Section 1-75(c)(5)). The regulations fail to require such prompt removal, allowing, at subsection 245.850(c), the overflow to remain in the reserve pits until 7 days “after completion of high volume horizontal hydraulic fracturing operations.” Certainly on a multi-well pad, hydraulic fracturing operations can continue for a month or more, meaning that the flowback fluid could be left sitting in the reserve pit, creating environmental risk, for much longer than a week. Revisions needed: First, require that drillers anticipate appropriate sized tanks for sufficient storage of flowback and produced water by establishing a method for tank capacity calculation. Second, clarify that wastewater must be removed from the pit within 7 days of the event that triggered the use of the pit rather than 7 days after fracking operations are complete, in accordance with the law.

Sincerely, Jonny Gill Chicago, IL 60605

Operators presumably have an economic incentive to do so in order to hold down the cost of tank storage. Compounding this incentive is the Department’s weakening of the statutory directive that fluids deposited in a reserve pit be removed within 7 days (Section 1-75(c)(5)). The regulations fail to require such prompt removal, allowing, at subsection 245.850(c), the overflow to remain in the reserve pits until 7 days “after completion of high volume horizontal hydraulic fracturing operations.” Certainly on a multi-well pad, hydraulic fracturing operations can continue for a month or more, meaning that the flowback fluid could be left sitting in the reserve pit, creating environmental risk, for much longer than a week. Revisions needed: First, require that drillers anticipate appropriate sized tanks for sufficient storage of flowback and produced water by establishing a method for tank capacity calculation. Second, clarify that wastewater must be removed from the pit within 7 days of the event that triggered the use of the pit rather than 7 days after fracking operations are complete, in accordance with the law.

Sincerely, Kelsey Chicago, IL 60631

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Section 1-75 of the Hydraulic Fracturing Regulator Act mandates that “excess hydraulic fracturing flowback captured for temporary storage in a reserve pit as provided in paragraph (2) of this subsection must be removed from the well site within 7 days.” But Section 245.850 of the proposed rules states, “Any excess hydraulic fracturing flowback captured for temporary storage in a reserve pit as provided in Section 245.825 must be removed from the well site or transferred to storage in above-ground tanks for later disposal or recycling within 7 days after completion of high volume horizontal hydraulic fracturing operations.” Problem: The amendment of “after completion of high volume horizontal hydraulic fracturing operations” opens the door for the potential abuse of emergency pits. Storage in closed tanks can be costly for the industry. An unscrupulous operator wanting to cut costs could simply claim that there was more flowback than expected and end up using open pits for storage for the duration of the fracking process. The clear intent of the statute is to ensure that wastewater is stored in tanks except in the emergency event of an unforeseeable overflow, in which case it is preferable that the overflow go to a pit than simply spill on the ground. But in such event, the overflow is expressly required in the statute to be removed within a week. Through omission and misinterpretation, the regulations are not implementing this statutory directive. Section 245.210(a)(11), requires that an applicant submit a Hydraulic Fracturing Fluids and Flowback Plan. The plan does not include requirements to ensure that tank capacity is accurately calculated. Without such method, there is nothing in the regulations to prevent operators from underestimating the size of the tanks they need, so as to make routine use of the reserve pit for the resulting overflows. Operators presumably have an economic incentive to do so in order to hold down the cost of tank storage. Compounding this incentive is the Department’s weakening of the statutory directive that fluids deposited in a reserve pit be removed within 7 days (Section 1-75(c)(5)). The regulations fail to require such prompt removal, allowing, at subsection 245.850(c), the overflow to remain in the reserve pits until 7 days “after completion of high volume horizontal hydraulic fracturing operations.” Certainly on a multi-well pad, hydraulic fracturing operations can continue for a month or more, meaning that the flowback fluid could be left sitting in the reserve pit, creating environmental risk, for much longer than a week. An unscrupulous operator wanting to cut costs could simply claim that there was more flowback than expected and end up using open pits for storage for the duration of the fracking process. The clear intent of the statute is to ensure that wastewater is stored in tanks except in the emergency event of an unforeseeable overflow, in which case it is preferable that the overflow go to a pit than simply spill on the ground. But in such event, the overflow is expressly required in the statute to be removed within a week. Through omission and misinterpretation, the regulations are not implementing this statutory directive. Section 245.210(a)(11), requires that an applicant submit a Hydraulic Fracturing Fluids and Flowback Plan. The plan does not include requirements to ensure that tank capacity is accurately calculated. Without such method, there is nothing in the regulations to prevent operators from underestimating the size of the tanks they need, so as to make routine use of the reserve pit for the resulting overflows. Operators presumably have an economic incentive to do so in order to hold down the cost of tank storage. Compounding this incentive is the Department’s weakening of the statutory directive that fluids deposited in a reserve pit be removed within 7 days (Section 1-75(c)(5)). The regulations fail to require such prompt removal, allowing, at subsection 245.850(c), the overflow to remain in the reserve pits until 7 days “after completion of high volume horizontal hydraulic fracturing operations.” Certainly on a multi-well pad, hydraulic fracturing operations can continue for a month or more, meaning that the flowback fluid could be left sitting in the reserve pit, creating environmental risk, for much longer than a week. Revisions needed: First, require that drillers anticipate appropriate sized tanks for sufficient storage of flowback and produced water by establishing a method for tank capacity calculation. Second, clarify that wastewater must be removed from the pit within 7 days of the event that triggered the use of the pit rather than 7 days after fracking operations are complete, in accordance with the law.

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Section 1-75 of the Hydraulic Fracturing Regulator Act mandates that “excess hydraulic fracturing flowback captured for temporary storage in a reserve pit as provided in paragraph (2) of this subsection must be removed from the well site within 7 days.” But Section 245.850 of the proposed rules states, “Any excess hydraulic fracturing flowback captured for temporary storage in a reserve pit as provided in Section 245.825 must be removed from the well site or transferred to storage in above-ground tanks for later disposal or recycling within 7 days after completion of high volume horizontal hydraulic fracturing operations.” Problem: The amendment of “after completion of high volume horizontal hydraulic fracturing operations” opens the door for the potential abuse of emergency pits. Storage in closed tanks can be costly for the industry. An unscrupulous operator wanting to cut costs could simply claim that there was more flowback than expected and end up using open pits for storage for the duration of the fracking process. The clear intent of the statute is to ensure that wastewater is stored in tanks except in the emergency event of an unforeseeable overflow, in which case it is preferable that the overflow go to a pit than simply spill on the ground. But in such event, the overflow is expressly required in the statute to be removed within a week.
