In reference to Subpart G: Chemical Disclosure; Trade Secrets

Section 245.720 Department Publication of Chemical Disclosures and Claims of Trade Secret

Section 245.720(d) of the Proposed Hydraulic Fracturing Regulatory Act administrative rules, states: IDNR allows permit applicants to withhold chemical disclosure information under a claim of “trade secret” if they can establish that (1) the information has not been published, disseminated, or otherwise become a matter of general public knowledge, and (2) the information has competitive value. Problems with this section: “Competitive value” is not defined in the various administrative code definitions. There is no IDNR administrative criteria provided which is the basis of “competitive value” other than, apparently, a self-identified one provided by the fracking operator. Why these are problems: Undefined and catch-all allowances for generic “competitive value” open the door for any and all dangerous chemicals to be undisclosed simply based on the operators desire to do so. Individual ingredients in the various chemical products used during hydraulic fracturing cannot be considered trade secrets under the criteria “competitive value”. The regulations should be revised to state that information on file with IDNR must be disclosed to the public. Raising such an allowance for a fracking operator to not disclose potentially dangerous chemicals based on “competitive value” automatically gives them more power than the basic claim of the law which is to protect the environment of Illinois. Revisions Needed: “Competitive value” must be fully defined within the rulemaking. Competitive value must not in any way supersede a determination of the public right to know and the basic legislative and Illinois Constitutional provision of a healthy and safe environment for its citizens. Any conflict between “competitive value” and the public right to know must be decided on the inherent protection of the citizens and the environment. The US EPA EPCRA regulations at 40 CFR 350 subpart A provide valuable guidance for fleshing out the language of the Act, in ways that are entirely consistent with it. We recommend in particular that the Department review the detailed showing required in 40 CFR 350.7, and import those requirements here as appropriate.

Sincerely, Dylan Amlin Chicago, IL 60640

In reference to Subpart G: Chemical Disclosure; Trade Secrets

Section 245.720 Department Publication of Chemical Disclosures and Claims of Trade Secret

Section 245.720(d) of the Proposed Hydraulic Fracturing Regulatory Act administrative rules, states: IDNR allows permit applicants to withhold chemical disclosure information under a claim of “trade secret” if they can establish that (1) the information has not been published, disseminated, or otherwise become a matter of general public knowledge, and (2) the information has competitive value. Problems with this section: “Competitive value” is not defined in the various administrative code definitions. There is no IDNR administrative criteria provided which is the basis of “competitive value” other than, apparently, a self-identified one provided by the fracking operator. Why these are problems: Undefined and catch-all allowances for generic “competitive value” open the door for any and all dangerous chemicals to be undisclosed simply based on the operators desire to do so. Individual ingredients in the various chemical products used during hydraulic fracturing cannot be considered trade secrets under the criteria “competitive value”. The regulations should be revised to state that information on file with IDNR must be disclosed to the public. Raising such an allowance for a fracking operator to not disclose potentially dangerous chemicals based on “competitive value” automatically gives them more power than the basic claim of the law which is to protect the environment of Illinois. Revisions Needed: “Competitive value” must be fully defined within the rulemaking. Competitive value must not in any way supersede a determination of the public right to know and the basic legislative and Illinois Constitutional provision of a healthy and safe environment for its citizens. Any conflict between “competitive value” and the public right to know must be decided on the inherent protection of the citizens and the environment. The US EPA EPCRA regulations at 40 CFR 350 subpart A provide valuable guidance for fleshing out the language of the Act, in ways that are entirely consistent with it. We recommend in particular that the Department review the detailed showing required in 40 CFR 350.7, and import those requirements here as appropriate.

Sincerely, Gerry Hoffman Chicago, IL 60657

Individual ingredients in the various chemical products used during hydraulic fracturing cannot be considered trade secrets under the criteria “competitive value”. The regulations should be revised to state that information on file with IDNR must be disclosed to the public. Raising such an allowance for a fracking operator to not disclose potentially dangerous chemicals based on “competitive value” automatically gives them more power than the basic claim of the law which is to protect the environment of Illinois. Revisions Needed: “Competitive value” must be fully defined within the rulemaking. Competitive value must not in any way supersede a determination of the public right to know and the basic legislative and Illinois Constitutional provision of a healthy and safe environment for its citizens. Any conflict between “competitive value” and the public right to know must be decided on the inherent protection of the citizens and the environment. The US EPA EPCRA regulations at 40 CFR 350 subpart A provide valuable guidance for fleshing out the language of the Act, in ways that are entirely consistent with it. We recommend in particular that the Department review the detailed showing required in 40 CFR 350.7, and import those requirements here as appropriate.

Sincerely, John Hunt Chicago, IL 60641

In reference to Subpart G: Chemical Disclosure; Trade Secrets

Section 245.720 Department Publication of Chemical Disclosures and Claims of Trade Secret

Section 245.720(d) of the Proposed Hydraulic Fracturing Regulatory Act administrative rules, states: IDNR allows permit applicants to withhold chemical disclosure information under a claim of “trade secret” if they can establish that (1) the information has not been published, disseminated, or otherwise become a matter of general public knowledge, and (2) the information has competitive value. Problems with this section: “Competitive value” is not defined in the various administrative code definitions. There is no IDNR administrative criteria provided which is the basis of “competitive value” other than, apparently, a self-identified one provided by the fracking operator. Why these are problems: Undefined and catch-all allowances for generic “competitive value” open the door for any and all dangerous chemicals to be undisclosed simply based on the operators desire to do so. Individual ingredients in the various chemical products used during hydraulic fracturing cannot be considered trade secrets under the criteria “competitive value”. The regulations should be revised to state that information on file with IDNR must be disclosed to the public. Raising such an allowance for a fracking operator to not disclose potentially dangerous chemicals based on “competitive value” automatically gives them more power than the basic claim of the law which is to protect the environment of Illinois. Revisions Needed: “Competitive value” must be fully defined within the rulemaking. Competitive value must not in any way supersede a determination of the public right to know and the basic legislative and Illinois Constitutional provision of a healthy and safe environment for its citizens. Any conflict between “competitive value” and the public right to know must be decided on the inherent protection of the citizens and the environment. The US EPA EPCRA regulations at 40 CFR 350 subpart A provide valuable guidance for fleshing out the language of the Act, in ways that are entirely consistent with it. Raising such an allowance for a fracking operator to not disclose potentially dangerous chemicals based on “competitive value” automatically gives them more power than the basic claim of the law which is to protect the environment of Illinois. Revisions Needed: “Competitive value” must be fully defined within the rulemaking. Competitive value must not in any way supersede a determination of the public right to know and the basic legislative and Illinois Constitutional provision of a healthy and safe environment for its citizens. Any conflict between “competitive value” and the public right to know must be decided on the inherent protection of the citizens and the environment.

Sincerely, Linda Green 422 East 450 North Rd MORRISONVILLE, IL 62546

In reference to Subpart G: Chemical Disclosure; Trade Secrets

Section 245.720 Department Publication of Chemical Disclosures and Claims of Trade Secret

Section 245.720(d) of the Proposed Hydraulic Fracturing Regulatory Act administrative rules, states: IDNR allows permit applicants to withhold chemical disclosure information under a claim of “trade secret” if they can establish that (1) the information has not been published, disseminated, or otherwise become a matter of general public knowledge, and (2) the information has competitive value. Problems with this section: “Competitive value” is not defined in the various administrative code definitions. There is no IDNR administrative criteria provided which is the basis of “competitive value” other than, apparently, a self-identified one provided by the fracking operator. Why these are problems: Undefined and catch-all allowances for generic “competitive value” open the door for any and all dangerous chemicals to be undisclosed simply based on the operators desire to do so. Individual ingredients in the various chemical products used during hydraulic fracturing cannot be considered trade secrets under the criteria “competitive value”. The regulations should be revised to state that information on file with IDNR must be disclosed to the public. Raising such an allowance for a fracking operator to not disclose potentially dangerous chemicals based on “competitive value” automatically gives them more power than the basic claim of the law which is to protect the environment of Illinois. Revisions Needed: “Competitive value” must be fully defined within the rulemaking. Competitive value must not in any way supersede a determination of the public right to know and the basic legislative and Illinois Constitutional provision of a healthy and safe environment for its citizens. Any conflict between “competitive value” and the public right to know must be decided on the inherent protection of the citizens and the environment.

Sincerely, Linda Green 422 East 450 North Rd MORRISONVILLE, IL 62546

Problems with this section: “Competitive value” is not defined in the various administrative code definitions. There is no IDNR administrative criteria provided which is the basis of “competitive value” other than, apparently, a self-identified one provided by the fracking operator. Why these are problems: Undefined and catch-all allowances for generic “competitive value” open the door for any and all dangerous chemicals to be undisclosed simply based on the operators desire to do so. Individual ingredients in the various chemical products used during hydraulic fracturing cannot be considered trade secrets under the criteria “competitive value”. The regulations should be revised to state that information on file with IDNR must be disclosed to the public. Raising such an allowance for a fracking operator to not disclose potentially dangerous chemicals based on “competitive value” automatically gives them more power than the basic claim of the law which is to protect the environment of Illinois. Revisions Needed: “Competitive value” must be fully defined within the rulemaking. Competitive value must not in any way supersede a determination of the public right to know and the basic legislative and Illinois Constitutional provision of a healthy and safe environment for its citizens. Any conflict between “competitive value” and the public right to know must be decided on the inherent protection of the citizens and the environment.

Sincerely, Mary Ellen Barbezat Elgin, IL 60120

Why these are problems: Undefined and catch-all allowances for generic “competitive value” open the door for any and all dangerous chemicals to be undisclosed simply based on the operators desire to do so. Individual ingredients in the various chemical products used during hydraulic fracturing cannot be considered trade secrets under the criteria “competitive value”. The regulations should be revised to state that information on file with IDNR must be disclosed to the public. Raising such an allowance for a fracking operator to not disclose potentially dangerous chemicals based on “competitive value” automatically gives them more power than the basic claim of the law which is to protect the environment of Illinois. Revisions Needed: “Competitive value” must be fully defined within the rulemaking. Competitive value must not in any way supersede a determination of the public right to know and the basic legislative and Illinois Constitutional provision of a healthy and safe environment for its citizens. Any conflict between “competitive value” and the public right to know must be decided on the inherent protection of the citizens and the environment. The US EPA EPCRA regulations at 40 CFR 350 subpart A provide valuable guidance for fleshing out the language of the Act, in ways that are entirely consistent with it. We recommend in particular that the Department review the detailed showing required in 40 CFR 350.7, and import those requirements here as appropriate.

Sincerely, Min Li Naperville, IL 60564

In reference to Subpart G: Chemical Disclosure; Trade Secrets

Section 245.720 Department Publication of Chemical Disclosures and Claims of Trade Secret

Section 245.720(d) of the Proposed Hydraulic Fracturing Regulatory Act administrative rules, states: IDNR allows permit applicants to withhold chemical disclosure information under a claim of “trade secret” if they can establish that (1) the information has not been published, disseminated, or otherwise become a matter of general public knowledge, and (2) the information has competitive value. Problems with this section: “Competitive value” is not defined in the various administrative code definitions. There is no IDNR administrative criteria provided which is the basis of “competitive value” other than, apparently, a self-identified one provided by the fracking operator. Why these are problems: Undefined and catch-all allowances for generic “competitive value” open the door for any and all dangerous chemicals to be undisclosed simply based on the operators desire to do so. Individual ingredients in the various chemical products used during hydraulic fracturing cannot be considered trade secrets under the criteria “competitive value”. The regulations should be revised to state that information on file with IDNR must be disclosed to the public. Raising such an allowance for a fracking operator to not disclose potentially dangerous chemicals based on “competitive value” automatically gives them more power than the basic claim of the law which is to protect the environment of Illinois. Revisions Needed: “Competitive value” must be fully defined within the rulemaking. Competitive value must not in any way supersede a determination of the public right to know and the basic legislative and Illinois Constitutional provision of a healthy and safe environment for its citizens. Any conflict between “competitive value” and the public right to know must be decided on the inherent protection of the citizens and the environment. The US EPA EPCRA regulations at 40 CFR 350 subpart A provide valuable guidance for fleshing out the language of the Act, in ways that are entirely consistent with it. Raising such an allowance for a fracking operator to not disclose potentially dangerous chemicals based on “competitive value” automatically gives them more power than the basic claim of the law which is to protect the environment of Illinois. Revisions Needed: “Competitive value” must be fully defined within the rulemaking. Competitive value must not in any way supersede a determination of the public right to know and the basic legislative and Illinois Constitutional provision of a healthy and safe environment for its citizens. Any conflict between “competitive value” and the public right to know must be decided on the inherent protection of the citizens and the environment. The US EPA EPCRA regulations at 40 CFR 350 subpart A provide valuable guidance for fleshing out the language of the Act, in ways that are entirely consistent with it. We recommend in particular that the Department review the detailed showing required in 40 CFR 350.7, and import those requirements here as appropriate.

Sincerely, Patrick Dexter Chicago, IL 60615

In reference to Subpart G: Chemical Disclosure; Trade Secrets

Section 245.720 Department Publication of Chemical Disclosures and Claims of Trade Secret

Section 245.720(d) of the Proposed Hydraulic Fracturing Regulatory Act administrative rules, states: IDNR allows permit applicants to withhold chemical disclosure information under a claim of “trade secret” if they can establish that (1) the information has not been published, disseminated, or otherwise become a matter of general public knowledge, and (2) the information has competitive value. Problems with this section: 1. “Competitive value” is not defined in the various administrative code definitions. 2. There is no IDNR administrative criteria provided which is the basis of “competitive value” other than, apparently, a self-identified one provided by the fracking operator. Why these are problems: 1. Undefined and catch-all allowances for generic “competitive value” open the door for any and all dangerous chemicals to be undisclosed simply based on the operators desire to do so. 2. Individual ingredients in the various chemical products used during hydraulic fracturing cannot be considered trade secrets under the criteria “competitive value”. The regulations should be revised to state that information on file with IDNR must be disclosed to the public. 3. Raising such an allowance for a fracking operator to not disclose potentially dangerous chemicals based on “competitive value” automatically gives them more power than the basic claim of the law which is to protect the environment of Illinois. Revisions Needed: 1. “Competitive value” must be fully defined within the rulemaking. 2. Competitive value must not in any way supersede a determination of the public right to know and the basic legislative and Illinois Constitutional provision of a healthy and safe environment for its citizens. 3. Any conflict between “competitive value” and the public right to know must be decided on the inherent protection of the citizens and the environment.

Sincerely, Patti Walker RR#2 (Box42a) Karbers Ridge, IL 62955

Individual ingredients in the various chemical products used during hydraulic fracturing cannot be considered trade secrets under the criteria “competitive value”. The regulations should be revised to state that information on file with IDNR must be disclosed to the public. Raising such an allowance for a fracking operator to not disclose potentially dangerous chemicals based on “competitive value” automatically gives them more power than the basic claim of the law which is to protect the environment of Illinois. Revisions Needed: “Competitive value” must be fully defined within the rulemaking. Competitive value must not in any way supersede a determination of the public right to know and the basic legislative and Illinois Constitutional provision of a healthy and safe environment for its citizens. Any conflict between “competitive value” and the public right to know must be decided on the inherent protection of the citizens and the environment. The US EPA EPCRA regulations at 40 CFR 350 subpart A provide valuable guidance for fleshing out the language of the Act, in ways that are entirely consistent with it. We recommend in particular that the Department review the detailed showing required in 40 CFR 350.7, and import those requirements here as appropriate.

Sincerely, Raj Kapoor Oak Park, IL 60302

In reference to Subpart G: Chemical Disclosure; Trade Secrets

Section 245.720 Department Publication of Chemical Disclosures and Claims of Trade Secret

Section 245.720(d) of the Proposed Hydraulic Fracturing Regulatory Act administrative rules, states: IDNR allows permit applicants to withhold chemical disclosure information under a claim of “trade secret” if they can establish that (1) the information has not been published, disseminated, or otherwise become a matter of general public knowledge, and (2) the information has competitive value. Problems with this section: 1. “Competitive value” is not defined in the various administrative code definitions. 2. There is no IDNR administrative criteria provided which is the basis of “competitive value” other than, apparently, a self-identified one provided by the fracking operator. Why these are problems: 1. Undefined and catch-all allowances for generic “competitive value” open the door for any and all dangerous chemicals to be undisclosed simply based on the operators desire to do so. 2. Individual ingredients in the various chemical products used during hydraulic fracturing cannot be considered trade secrets under the criteria “competitive value”. The regulations should be revised to state that information on file with IDNR must be disclosed to the public. 3. Raising such an allowance for a fracking operator to not disclose potentially dangerous chemicals based on “competitive value” automatically gives them more power than the basic claim of the law which is to protect the environment of Illinois. Revisions Needed: 1. “Competitive value” must be fully defined within the rulemaking. 2. Competitive value must not in any way supersede a determination of the public right to know and the basic legislative and Illinois Constitutional provision of a healthy and safe environment for its citizens. 3. Any conflict between “competitive value” and the public right to know must be decided on the inherent protection of the citizens and the environment.

Competitive value must not in any way supersede a determination of the public right to know and the basic legislative and Illinois Constitutional provision of a healthy and safe environment for its citizens. Any conflict between “competitive value” and the public right to know must be decided on the inherent protection of the citizens and the environment. The US EPA EPCRA regulations at 40 CFR 350 subpart A provide valuable guidance for fleshing out the language of the Act, in ways that are entirely consistent with it. We recommend in particular that the Department review the detailed showing required in 40 CFR 350.7, and import those requirements here as appropriate.

Sincerely, Sarah Quesnell Chicago, IL 60605

In reference to Subpart G: Chemical Disclosure; Trade Secrets

Section 245.720 Department Publication of Chemical Disclosures and Claims of Trade Secret

Section 245.720(d) of the Proposed Hydraulic Fracturing Regulatory Act administrative rules, states: IDNR allows permit applicants to withhold chemical disclosure information under a claim of “trade secret” if they can establish that (1) the information has not been published, disseminated, or otherwise become a matter of general public knowledge, and (2) the information has competitive value. Problems with this section: “Competitive value” is not defined in the various administrative code definitions. There is no IDNR administrative criteria provided which is the basis of “competitive value” other than, apparently, a self-identified one provided by the fracking operator. Why these are problems: Undefined and catch-all allowances for generic “competitive value” open the door for any and all dangerous chemicals to be undisclosed simply based on the operators desire to do so. Individual ingredients in the various chemical products used during hydraulic fracturing cannot be considered trade secrets under the criteria “competitive value”. The regulations should be revised to state that information on file with IDNR must be disclosed to the public. Raising such an allowance for a fracking operator to not disclose potentially dangerous chemicals based on “competitive value” automatically gives them more power than the basic claim of the law which is to protect the environment of Illinois. Revisions Needed: “Competitive value” must be fully defined within the rulemaking. Competitive value must not in any way supersede a determination of the public right to know and the basic legislative and Illinois Constitutional provision of a healthy and safe environment for its citizens. Any conflict between “competitive value” and the public right to know must be decided on the inherent protection of the citizens and the environment. The US EPA EPCRA regulations at 40 CFR 350 subpart A provide valuable guidance for fleshing out the language of the Act, in ways that are entirely consistent with it. We recommend in particular that the Department review the detailed showing required in 40 CFR 350.7, and import those requirements here as appropriate.

Section 245.720(d) of the Proposed Hydraulic Fracturing Regulatory Act administrative rules, states: IDNR allows permit applicants to withhold chemical disclosure information under a claim of “trade secret” if they can establish that (1) the information has not been published, disseminated, or otherwise become a matter of general public knowledge, and (2) the information has competitive value. Problems with this section: “Competitive value” is not defined in the various administrative code definitions. There is no IDNR administrative criteria provided which is the basis of “competitive value” other than, apparently, a self-identified one provided by the fracking operator. Why these are problems: Undefined and catch-all allowances for generic “competitive value” open the door for any and all dangerous chemicals to be undisclosed simply based on the operators desire to do so. Individual ingredients in the various chemical products used during hydraulic fracturing cannot be considered trade secrets under the criteria “competitive value”. The regulations should be revised to state that information on file with IDNR must be disclosed to the public. Raising such an allowance for a fracking operator to not disclose potentially dangerous chemicals based on “competitive value” automatically gives them more power than the basic claim of the law which is to protect the environment of Illinois. Revisions Needed: “Competitive value” must be fully defined within the rulemaking. Competitive value must not in any way supersede a determination of the public right to know and the basic legislative and Illinois Constitutional provision of a healthy and safe environment for its citizens. Any conflict between “competitive value” and the public right to know must be decided on the inherent protection of the citizens and the environment. The US EPA EPCRA regulations at 40 CFR 350 subpart A provide valuable guidance for fleshing out the language of the Act, in ways that are entirely consistent with it. We recommend in particular that the Department review the detailed showing required in 40 CFR 350.7, and import those requirements here as appropriate.

Sincerely, Simone Serhan Chicago, IL 60605

In reference to Subpart G: Chemical Disclosure; Trade Secrets

Section 245.720 Department Publication of Chemical Disclosures and Claims of Trade Secret

Section 245.720(d) of the Proposed Hydraulic Fracturing Regulatory Act administrative rules, states: IDNR allows permit applicants to withhold chemical disclosure information under a claim of “trade secret” if they can establish that (1) the information has not been published, disseminated, or otherwise become a matter of general public knowledge, and (2) the information has competitive value. Problems with this section: “Competitive value” is not defined in the various administrative code definitions. There is no IDNR administrative criteria provided which is the basis of “competitive value” other than, apparently, a self-identified one provided by the fracking operator. Why these are problems: Undefined and catch-all allowances for generic “competitive value” open the door for any and all dangerous chemicals to be undisclosed simply based on the operators desire to do so. Individual ingredients in the various chemical products used during hydraulic fracturing cannot be considered trade secrets under the criteria “competitive value”. The regulations should be revised to state that information on file with IDNR must be disclosed to the public. Raising such an allowance for a fracking operator to not disclose potentially dangerous chemicals based on “competitive value” automatically gives them more power than the basic claim of the law which is to protect the environment of Illinois. Revisions Needed: “Competitive value” must be fully defined within the rulemaking. Competitive value must not in any way supersede a determination of the public right to know and the basic legislative and Illinois Constitutional provision of a healthy and safe environment for its citizens. Any conflict between “competitive value” and the public right to know must be decided on the inherent protection of the citizens and the environment. The US EPA EPCRA regulations at 40 CFR 350 subpart A provide valuable guidance for fleshing out the language of the Act, in ways that are entirely consistent with it. We recommend in particular that the Department review the detailed showing required in 40 CFR 350.7, and import those requirements here as appropriate.

Sincerely, Veronica Murashige Chicago, IL 60637

In reference to Subpart G: Chemical Disclosure; Trade Secrets

### Section 245.730 Trade Secret Disclosure to Health Professional

Dear IDNR, The proposed language concerning disclosure of trade secret-protected information to health professionals is neither consistent with the statute nor protective of the public. Right to Know - Section 1-77(l) of the Act is clear that information shall be provided, as needed, to health professionals who demonstrate a need for it. Yet, section 245.730 of the Rules diminishes the language of the Act, stating only that the Department "may" provide information to health professionals who demonstrate a need for it. Limitation to "normal business hours. - Subsection 245.730(b)(1) of the Rules states, in the event of an emergency, that a health professional may call the Department during "normal business hours." For an emergency that occurs after hours, the Rules suggest calling the trade secret holder. This is inadequate. The Department should provide a 24- hour hotline for emergency calls pursuant to this section. "Trade Secret Holder." - Subsection 245.730(b)(2) of the Rules allows a health professional to seek the necessary information from a "trade secret holder," but there is no means provided for the health professional to know who the trade secret holder is, or what phone number to use to reach it. Furthermore, this provision is found nowhere in the statute, seemingly adding another unnecessary burden on the health professional. Lack of a time limit for the Department's response. - The Department should abide by the same 3-hour time limit for a response that applies to trade secret holders pursuant to 245.730(b)(2). Disclosure of names receiving trade secret information. - Subsection 245.730(e) of the rules requires that health providers report to the trade secret holder the names of persons to whom the protected information was disclosed. This requirement is found nowhere in the statute. It is inappropriate to burden health professionals with such an obligation in the absence of statutory authorization to do so. You must rewrite the section to comply with the strongest interpretation of 1-77 of the Statute including 24-hour accessibility. Do not require that health providers report names of persons to whom protected information was disclosed as this was not required in the statute. Kurt

Sincerely, Kurt Brian Witteman 425 S Wabash Ave WBRH 41 Chicago, IL 60605

Furthermore, this provision is found nowhere in the statute, seemingly adding another unnecessary burden on the health professional. Lack of a time limit for the Department’s response. The Department should abide by the same 3-hour time limit for a response that applies to trade secret holders pursuant to 245.730(b)(2). Disclosure of names receiving trade secret information. Subsection 245.730(e) of the rules requires that health providers report to the trade secret holder the names of persons to whom the protected information was disclosed. This requirement is found nowhere in the statute. It is inappropriate to burden health professionals with such an obligation in the absence of statutory authorization to do so. Revisions Needed: Rewrite the section to comply with the strongest interpretation of 1-77 of the Statute including 24-hour accessibility. Do not require that health providers report names of persons to whom protected information was disclosed as this was not required in the statute.

Sincerely, B. E. Murphy 458 Tahoe Park Forest, IL 60466

### Section 245.730 Trade Secret Disclosure to Health Professional

Subpart G: Chemical Disclosure; Trade Secrets (245.700-245.730) 245.730 Trade Secret Disclosure to Health Professional The proposed language concerning disclosure of trade secret-protected information to health professionals is neither consistent with the statute nor protective of the public. Right to Know. Section 1-77(l) of the Act is clear that information shall be provided, as needed, to health professionals who demonstrate a need for it. Yet, section 245.730 of the Rules diminishes the language of the Act, stating only that the Department “may” provide information to health professionals who demonstrate a need for it. Limitation to “normal business hours.” Subsection 245.730(b)(1) of the Rules states, in the event of an emergency, that a health professional may call the Department during “normal business hours.” For an emergency that occurs after hours, the Rules suggest calling the trade secret holder. This is inadequate. The Department should provide a 24- hour hotline for emergency calls pursuant to this section. “Trade Secret Holder.” Subsection 245.730(b)(2) of the Rules allows a health professional to seek the necessary information from a “trade secret holder,” but there is no means provided for the health professional to know who the trade secret holder is, or what phone number to use to reach it. Furthermore, this provision is found nowhere in the statute, seemingly adding another unnecessary burden on the health professional. Lack of a time limit for the Department’s response. The Department should abide by the same 3-hour time limit for a response that applies to trade secret holders pursuant to 245.730(b)(2). Disclosure of names receiving trade secret information. Subsection 245.730(e) of the rules requires that health providers report to the trade secret holder the names of persons to whom the protected information was disclosed. This requirement is found nowhere in the statute. It is inappropriate to burden health professionals with such an obligation in the absence of statutory authorization to do so. This is inadequate. The Department should provide a 24- hour hotline for emergency calls pursuant to this section. “Trade Secret Holder.” Subsection 245.730(b)(2) of the Rules allows a health professional to seek the necessary information from a “trade secret holder,” but there is no means provided for the health professional to know who the trade secret holder is, or what phone number to use to reach it. Furthermore, this provision is found nowhere in the statute, seemingly adding another unnecessary burden on the health professional. Lack of a time limit for the Department’s response. The Department should abide by the same 3-hour time limit for a response that applies to trade secret holders pursuant to 245.730(b)(2). Disclosure of names receiving trade secret information. Subsection 245.730(e) of the rules requires that health providers report to the trade secret holder the names of persons to whom the protected information was disclosed. This requirement is found nowhere in the statute. It is inappropriate to burden health professionals with such an obligation in the absence of statutory authorization to do so. Revisions Needed: Rewrite the section to comply with the strongest interpretation of 1-77 of the Statute including 24-hour accessibility. Do not require that health providers report names of persons to whom protected information was disclosed as this was not required in the statute.

Sincerely, Anica Washington Chicago, IL 60619

### Section 245.730 Trade Secret Disclosure to Health Professional

The proposed language concerning disclosure of trade secret-protected information to health professionals is neither consistent with the statute nor protective of the public. Right to Know. Section 1-77(l) of the Act is clear that information shall be provided, as needed, to health professionals who demonstrate a need for it. Yet, section 245.730 of the Rules diminishes the language of the Act, stating only that the Department “may” provide information to health professionals who demonstrate a need for it. Limitation to “normal business hours.” Subsection 245.730(b)(1) of the Rules states, in the event of an emergency, that a health professional may call the Department during “normal business hours.” For an emergency that occurs after hours, the Rules suggest calling the trade secret holder. This is inadequate. The Department should provide a 24- hour hotline for emergency calls pursuant to this section. “Trade Secret Holder.” Subsection 245.730(b)(2) of the Rules allows a health professional to seek the necessary information from a “trade secret holder,” but there is no means provided for the health professional to know who the trade secret holder is, or what phone number to use to reach it. Furthermore, this provision is found nowhere in the statute, seemingly adding another unnecessary burden on the health professional. Lack of a time limit for the Department’s response. The Department should abide by the same 3-hour time limit for a response that applies to trade secret holders pursuant to 245.730(b)(2). Disclosure of names receiving trade secret information. Subsection 245.730(e) of the rules requires that health providers report to the trade secret holder the names of persons to whom the protected information was disclosed. This requirement is found nowhere in the statute. It is inappropriate to burden health professionals with such an obligation in the absence of statutory authorization to do so. Revisions Needed: Rewrite the section to comply with the strongest interpretation of 1-77 of the Statute including 24-hour accessibility. Do not require that health providers report names of persons to whom protected information was disclosed as this was not required in the statute.

The Department should provide a 24- hour hotline for emergency calls pursuant to this section. “Trade Secret Holder.” Subsection 245.730(b)(2) of the Rules allows a health professional to seek the necessary information from a “trade secret holder,” but there is no means provided for the health professional to know who the trade secret holder is, or what phone number to use to reach it. Furthermore, this provision is found nowhere in the statute, seemingly adding another unnecessary burden on the health professional. Lack of a time limit for the Department’s response. The Department should abide by the same 3-hour time limit for a response that applies to trade secret holders pursuant to 245.730(b)(2). Disclosure of names receiving trade secret information. Subsection 245.730(e) of the rules requires that health providers report to the trade secret holder the names of persons to whom the protected information was disclosed. This requirement is found nowhere in the statute. It is inappropriate to burden health professionals with such an obligation in the absence of statutory authorization to do so. Revisions Needed: Rewrite the section to comply with the strongest interpretation of 1-77 of the Statute including 24-hour accessibility. Do not require that health providers report names of persons to whom protected information was disclosed as this was not required in the statute.

Sincerely, Brian Menzel Chicago, IL 60608

### Section 245.730 Trade Secret Disclosure to Health Professional

The proposed language concerning disclosure of trade secret-protected information to health professionals is neither consistent with the statute nor protective of the public. Right to Know. Section 1-77(l) of the Act is clear that information shall be provided, as needed, to health professionals who demonstrate a need for it. Yet, section 245.730 of the Rules diminishes the language of the Act, stating only that the Department “may” provide information to health professionals who demonstrate a need for it. Limitation to “normal business hours.” Subsection 245.730(b)(1) of the Rules states, in the event of an emergency, that a health professional may call the Department during “normal business hours.” For an emergency that occurs after hours, the Rules suggest calling the trade secret holder. This is inadequate. The Department should provide a 24- hour hotline for emergency calls pursuant to this section. “Trade Secret Holder.” Subsection 245.730(b)(2) of the Rules allows a health professional to seek the necessary information from a “trade secret holder,” but there is no means provided for the health professional to know who the trade secret holder is, or what phone number to use to reach it. Furthermore, this provision is found nowhere in the statute, seemingly adding another unnecessary burden on the health professional. Lack of a time limit for the Department’s response. The Department should abide by the same 3-hour time limit for a response that applies to trade secret holders pursuant to 245.730(b)(2). Disclosure of names receiving trade secret information. Subsection 245.730(e) of the rules requires that health providers report to the trade secret holder the names of persons to whom the protected information was disclosed. This requirement is found nowhere in the statute. It is inappropriate to burden health professionals with such an obligation in the absence of statutory authorization to do so. Revisions Needed: Rewrite the section to comply with the strongest interpretation of 1-77 of the Statute including 24-hour accessibility. Do not require that health providers report names of persons to whom protected information was disclosed as this was not required in the statute.

The Department should provide a 24- hour hotline for emergency calls pursuant to this section. “Trade Secret Holder.” Subsection 245.730(b)(2) of the Rules allows a health professional to seek the necessary information from a “trade secret holder,” but there is no means provided for the health professional to know who the trade secret holder is, or what phone number to use to reach it. Furthermore, this provision is found nowhere in the statute, seemingly adding another unnecessary burden on the health professional. Lack of a time limit for the Department’s response. The Department should abide by the same 3-hour time limit for a response that applies to trade secret holders pursuant to 245.730(b)(2). Disclosure of names receiving trade secret information. Subsection 245.730(e) of the rules requires that health providers report to the trade secret holder the names of persons to whom the protected information was disclosed. This requirement is found nowhere in the statute. It is inappropriate to burden health professionals with such an obligation in the absence of statutory authorization to do so. Revisions Needed: Rewrite the section to comply with the strongest interpretation of 1-77 of the Statute including 24-hour accessibility. Do not require that health providers report names of persons to whom protected information was disclosed as this was not required in the statute.

Sincerely, Diamond Hartwell Chicago, IL 60605

### Section 245.730 Trade Secret Disclosure to Health Professional

The proposed language concerning disclosure of trade secret-protected information to health professionals is neither consistent with the statute nor protective of the public. Right to Know. Section 1-77(l) of the Act is clear that information shall be provided, as needed, to health professionals who demonstrate a need for it. Yet, section 245.730 of the Rules diminishes the language of the Act, stating only that the Department “may” provide information to health professionals who demonstrate a need for it. Limitation to “normal business hours.” Subsection 245.730(b)(1) of the Rules states, in the event of an emergency, that a health professional may call the Department during “normal business hours.” For an emergency that occurs after hours, the Rules suggest calling the trade secret holder. This is inadequate. The Department should provide a 24- hour hotline for emergency calls pursuant to this section. “Trade Secret Holder.” Subsection 245.730(b)(2) of the Rules allows a health professional to seek the necessary information from a “trade secret holder,” but there is no means provided for the health professional to know who the trade secret holder is, or what phone number to use to reach it. Furthermore, this provision is found nowhere in the statute, seemingly adding another unnecessary burden on the health professional. Lack of a time limit for the Department’s response. The Department should abide by the same 3-hour time limit for a response that applies to trade secret holders pursuant to 245.730(b)(2). Disclosure of names receiving trade secret information. Subsection 245.730(e) of the rules requires that health providers report to the trade secret holder the names of persons to whom the protected information was disclosed. This requirement is found nowhere in the statute. It is inappropriate to burden health professionals with such an obligation in the absence of statutory authorization to do so. Revisions Needed: Rewrite the section to comply with the strongest interpretation of 1-77 of the Statute including 24-hour accessibility. The Department should provide a 24- hour hotline for emergency calls pursuant to this section. “Trade Secret Holder.” Subsection 245.730(b)(2) of the Rules allows a health professional to seek the necessary information from a “trade secret holder,” but there is no means provided for the health professional to know who the trade secret holder is, or what phone number to use to reach it. Furthermore, this provision is found nowhere in the statute, seemingly adding another unnecessary burden on the health professional. Lack of a time limit for the Department’s response. The Department should abide by the same 3-hour time limit for a response that applies to trade secret holders pursuant to 245.730(b)(2). Disclosure of names receiving trade secret information. Subsection 245.730(e) of the rules requires that health providers report to the trade secret holder the names of persons to whom the protected information was disclosed. This requirement is found nowhere in the statute. It is inappropriate to burden health professionals with such an obligation in the absence of statutory authorization to do so. Revisions Needed: Rewrite the section to comply with the strongest interpretation of 1-77 of the Statute including 24-hour accessibility. Do not require that health providers report names of persons to whom protected information was disclosed as this was not required in the statute.

Sincerely, Elizabeth Scrafford chicago, IL 60626

### Section 245.730 Trade Secret Disclosure to Health Professional

The proposed language concerning disclosure of trade secret-protected information to health professionals is neither consistent with the statute nor protective of the public. Right to Know. Section 1-77(l) of the Act is clear that information shall be provided, as needed, to health professionals who demonstrate a need for it. Yet, section 245.730 of the Rules diminishes the language of the Act, stating only that the Department “may” provide information to health professionals who demonstrate a need for it. Limitation to “normal business hours.” Subsection 245.730(b)(1) of the Rules states, in the event of an emergency, that a health professional may call the Department during “normal business hours.” For an emergency that occurs after hours, the Rules suggest calling the trade secret holder. This is inadequate. The Department should provide a 24- hour hotline for emergency calls pursuant to this section. “Trade Secret Holder.” Subsection 245.730(b)(2) of the Rules allows a health professional to seek the necessary information from a “trade secret holder,” but there is no means provided for the health professional to know who the trade secret holder is, or what phone number to use to reach it. Furthermore, this provision is found nowhere in the statute, seemingly adding another unnecessary burden on the health professional. Lack of a time limit for the Department’s response. The Department should abide by the same 3-hour time limit for a response that applies to trade secret holders pursuant to 245.730(b)(2). Disclosure of names receiving trade secret information. Subsection 245.730(e) of the rules requires that health providers report to the trade secret holder the names of persons to whom the protected information was disclosed. This requirement is found nowhere in the statute. It is inappropriate to burden health professionals with such an obligation in the absence of statutory authorization to do so. Revisions Needed: Rewrite the section to comply with the strongest interpretation of 1-77 of the Statute including 24-hour accessibility. Do not require that health providers report names of persons to whom protected information was disclosed as this was not required in the statute.

This is inadequate. The Department should provide a 24- hour hotline for emergency calls pursuant to this section. “Trade Secret Holder.” Subsection 245.730(b)(2) of the Rules allows a health professional to seek the necessary information from a “trade secret holder,” but there is no means provided for the health professional to know who the trade secret holder is, or what phone number to use to reach it. Furthermore, this provision is found nowhere in the statute, seemingly adding another unnecessary burden on the health professional. Lack of a time limit for the Department’s response. The Department should abide by the same 3-hour time limit for a response that applies to trade secret holders pursuant to 245.730(b)(2). Disclosure of names receiving trade secret information. Subsection 245.730(e) of the rules requires that health providers report to the trade secret holder the names of persons to whom the protected information was disclosed. This requirement is found nowhere in the statute. It is inappropriate to burden health professionals with such an obligation in the absence of statutory authorization to do so. Revisions Needed: Rewrite the section to comply with the strongest interpretation of 1-77 of the Statute including 24-hour accessibility. Do not require that health providers report names of persons to whom protected information was disclosed as this was not required in the statute.

Sincerely, Gianna Chacon 525 South State Street (Apt. 1326) Chicago, IL 60605

### Section 245.730 Trade Secret Disclosure to Health Professional

The proposed language concerning disclosure of trade secret-protected information to health professionals is neither consistent with the statute nor protective of the public. Right to Know. Section 1-77(l) of the Act is clear that information shall be provided, as needed, to health professionals who demonstrate a need for it. Yet, section 245.730 of the Rules diminishes the language of the Act, stating only that the Department “may” provide information to health professionals who demonstrate a need for it. Limitation to “normal business hours.” Subsection 245.730(b)(1) of the Rules states, in the event of an emergency, that a health professional may call the Department during “normal business hours.” For an emergency that occurs after hours, the Rules suggest calling the trade secret holder. This is inadequate. The Department should provide a 24- hour hotline for emergency calls pursuant to this section. “Trade Secret Holder.” Subsection 245.730(b)(2) of the Rules allows a health professional to seek the necessary information from a “trade secret holder,” but there is no means provided for the health professional to know who the trade secret holder is, or what phone number to use to reach it. Furthermore, this provision is found nowhere in the statute, seemingly adding another unnecessary burden on the health professional. Lack of a time limit for the Department’s response. The Department should abide by the same 3-hour time limit for a response that applies to trade secret holders pursuant to 245.730(b)(2). Disclosure of names receiving trade secret information. Subsection 245.730(e) of the rules requires that health providers report to the trade secret holder the names of persons to whom the protected information was disclosed. This requirement is found nowhere in the statute. It is inappropriate to burden health professionals with such an obligation in the absence of statutory authorization to do so. Revisions Needed: Rewrite the section to comply with the strongest interpretation of 1-77 of the Statute including 24-hour accessibility. This is inadequate. The Department should provide a 24- hour hotline for emergency calls pursuant to this section. “Trade Secret Holder.” Subsection 245.730(b)(2) of the Rules allows a health professional to seek the necessary information from a “trade secret holder,” but there is no means provided for the health professional to know who the trade secret holder is, or what phone number to use to reach it. Furthermore, this provision is found nowhere in the statute, seemingly adding another unnecessary burden on the health professional. Lack of a time limit for the Department’s response. The Department should abide by the same 3-hour time limit for a response that applies to trade secret holders pursuant to 245.730(b)(2). Disclosure of names receiving trade secret information. Subsection 245.730(e) of the rules requires that health providers report to the trade secret holder the names of persons to whom the protected information was disclosed. This requirement is found nowhere in the statute. It is inappropriate to burden health professionals with such an obligation in the absence of statutory authorization to do so. Revisions Needed: Rewrite the section to comply with the strongest interpretation of 1-77 of the Statute including 24-hour accessibility. Do not require that health providers report names of persons to whom protected information was disclosed as this was not required in the statute.

Sincerely, Jeff Engstrom Urbana, IL 61801

### Section 245.730 Trade Secret Disclosure to Health Professional

The proposed language concerning disclosure of trade secret-protected information to health professionals is neither consistent with the statute nor protective of the public. Right to Know. Section 1-77(l) of the Act is clear that information shall be provided, as needed, to health professionals who demonstrate a need for it. Yet, section 245.730 of the Rules diminishes the language of the Act, stating only that the Department “may” provide information to health professionals who demonstrate a need for it. Limitation to “normal business hours.” Subsection 245.730(b)(1) of the Rules states, in the event of an emergency, that a health professional may call the Department during “normal business hours.” For an emergency that occurs after hours, the Rules suggest calling the trade secret holder. This is inadequate. The Department should provide a 24- hour hotline for emergency calls pursuant to this section. “Trade Secret Holder.” Subsection 245.730(b)(2) of the Rules allows a health professional to seek the necessary information from a “trade secret holder,” but there is no means provided for the health professional to know who the trade secret holder is, or what phone number to use to reach it. Furthermore, this provision is found nowhere in the statute, seemingly adding another unnecessary burden on the health professional. Lack of a time limit for the Department’s response. The Department should abide by the same 3-hour time limit for a response that applies to trade secret holders pursuant to 245.730(b)(2). Disclosure of names receiving trade secret information. Subsection 245.730(e) of the rules requires that health providers report to the trade secret holder the names of persons to whom the protected information was disclosed. This requirement is found nowhere in the statute. It is inappropriate to burden health professionals with such an obligation in the absence of statutory authorization to do so. Revisions Needed: Rewrite the section to comply with the strongest interpretation of 1-77 of the Statute including 24-hour accessibility. Do not require that health providers report names of persons to whom protected information was disclosed as this was not required in the statute.

The Department should provide a 24- hour hotline for emergency calls pursuant to this section. “Trade Secret Holder.” Subsection 245.730(b)(2) of the Rules allows a health professional to seek the necessary information from a “trade secret holder,” but there is no means provided for the health professional to know who the trade secret holder is, or what phone number to use to reach it. Furthermore, this provision is found nowhere in the statute, seemingly adding another unnecessary burden on the health professional. Lack of a time limit for the Department’s response. The Department should abide by the same 3-hour time limit for a response that applies to trade secret holders pursuant to 245.730(b)(2). Disclosure of names receiving trade secret information. Subsection 245.730(e) of the rules requires that health providers report to the trade secret holder the names of persons to whom the protected information was disclosed. This requirement is found nowhere in the statute. It is inappropriate to burden health professionals with such an obligation in the absence of statutory authorization to do so. Revisions Needed: Rewrite the section to comply with the strongest interpretation of 1-77 of the Statute including 24-hour accessibility. Do not require that health providers report names of persons to whom protected information was disclosed as this was not required in the statute.

Sincerely, Kiehlor Mack Chicago, IL 60637

### Section 245.730 Trade Secret Disclosure to Health Professional

The proposed language concerning disclosure of trade secret-protected information to health professionals is neither consistent with the statute nor protective of the public. Right to Know. Section 1-77(l) of the Act is clear that information shall be provided, as needed, to health professionals who demonstrate a need for it. Yet, section 245.730 of the Rules diminishes the language of the Act, stating only that the Department “may” provide information to health professionals who demonstrate a need for it. Limitation to “normal business hours.” Subsection 245.730(b)(1) of the Rules states, in the event of an emergency, that a health professional may call the Department during “normal business hours.” For an emergency that occurs after hours, the Rules suggest calling the trade secret holder. This is inadequate. The Department should provide a 24- hour hotline for emergency calls pursuant to this section. “Trade Secret Holder.” Subsection 245.730(b)(2) of the Rules allows a health professional to seek the necessary information from a “trade secret holder,” but there is no means provided for the health professional to know who the trade secret holder is, or what phone number to use to reach it. Furthermore, this provision is found nowhere in the statute, seemingly adding another unnecessary burden on the health professional. Lack of a time limit for the Department’s response. The Department should abide by the same 3-hour time limit for a response that applies to trade secret holders pursuant to 245.730(b)(2). Disclosure of names receiving trade secret information. Subsection 245.730(e) of the rules requires that health providers report to the trade secret holder the names of persons to whom the protected information was disclosed. This requirement is found nowhere in the statute. It is inappropriate to burden health professionals with such an obligation in the absence of statutory authorization to do so. Revisions Needed: Rewrite the section to comply with the strongest interpretation of 1-77 of the Statute including 24-hour accessibility. The Department should provide a 24- hour hotline for emergency calls pursuant to this section. “Trade Secret Holder.” Subsection 245.730(b)(2) of the Rules allows a health professional to seek the necessary information from a “trade secret holder,” but there is no means provided for the health professional to know who the trade secret holder is, or what phone number to use to reach it. Furthermore, this provision is found nowhere in the statute, seemingly adding another unnecessary burden on the health professional. Lack of a time limit for the Department’s response. The Department should abide by the same 3-hour time limit for a response that applies to trade secret holders pursuant to 245.730(b)(2). Disclosure of names receiving trade secret information. Subsection 245.730(e) of the rules requires that health providers report to the trade secret holder the names of persons to whom the protected information was disclosed. This requirement is found nowhere in the statute. It is inappropriate to burden health professionals with such an obligation in the absence of statutory authorization to do so. Revisions Needed: Rewrite the section to comply with the strongest interpretation of 1-77 of the Statute including 24-hour accessibility. Do not require that health providers report names of persons to whom protected information was disclosed as this was not required in the statute.

Sincerely, Lexington Lawson Chicago, IL 60640

### Section 245.730 Trade Secret Disclosure to Health Professional

The proposed language concerning disclosure of trade secret-protected information to health professionals is neither consistent with the statute nor protective of the public. Right to Know. Section 1-77(l) of the Act is clear that information shall be provided, as needed, to health professionals who demonstrate a need for it. Yet, section 245.730 of the Rules diminishes the language of the Act, stating only that the Department “may” provide information to health professionals who demonstrate a need for it. Limitation to “normal business hours.” Subsection 245.730(b)(1) of the Rules states, in the event of an emergency, that a health professional may call the Department during “normal business hours.” For an emergency that occurs after hours, the Rules suggest calling the trade secret holder. This is inadequate. The Department should provide a 24- hour hotline for emergency calls pursuant to this section. “Trade Secret Holder.” Subsection 245.730(b)(2) of the Rules allows a health professional to seek the necessary information from a “trade secret holder,” but there is no means provided for the health professional to know who the trade secret holder is, or what phone number to use to reach it. Furthermore, this provision is found nowhere in the statute, seemingly adding another unnecessary burden on the health professional. Lack of a time limit for the Department’s response. The Department should abide by the same 3-hour time limit for a response that applies to trade secret holders pursuant to 245.730(b)(2). Disclosure of names receiving trade secret information. Subsection 245.730(e) of the rules requires that health providers report to the trade secret holder the names of persons to whom the protected information was disclosed. This requirement is found nowhere in the statute. It is inappropriate to burden health professionals with such an obligation in the absence of statutory authorization to do so. Revisions Needed: Rewrite the section to comply with the strongest interpretation of 1-77 of the Statute including 24-hour accessibility. Do not require that health providers report names of persons to whom protected information was disclosed as this was not required in the statute.

This is inadequate. The Department should provide a 24- hour hotline for emergency calls pursuant to this section. “Trade Secret Holder.” Subsection 245.730(b)(2) of the Rules allows a health professional to seek the necessary information from a “trade secret holder,” but there is no means provided for the health professional to know who the trade secret holder is, or what phone number to use to reach it. Furthermore, this provision is found nowhere in the statute, seemingly adding another unnecessary burden on the health professional. Lack of a time limit for the Department’s response. The Department should abide by the same 3-hour time limit for a response that applies to trade secret holders pursuant to 245.730(b)(2). Disclosure of names receiving trade secret information. Subsection 245.730(e) of the rules requires that health providers report to the trade secret holder the names of persons to whom the protected information was disclosed. This requirement is found nowhere in the statute. It is inappropriate to burden health professionals with such an obligation in the absence of statutory authorization to do so. Revisions Needed: Rewrite the section to comply with the strongest interpretation of 1-77 of the Statute including 24-hour accessibility. Do not require that health providers report names of persons to whom protected information was disclosed as this was not required in the statute.

Sincerely, Matt Chappell Tuscola, IL 61953

### Section 245.730 Trade Secret Disclosure to Health Professional

The proposed language concerning disclosure of trade secret-protected information to health professionals is neither consistent with the statute nor protective of the public. Right to Know. Section 1-77(l) of the Act is clear that information shall be provided, as needed, to health professionals who demonstrate a need for it. Yet, section 245.730 of the Rules diminishes the language of the Act, stating only that the Department “may” provide information to health professionals who demonstrate a need for it. Limitation to “normal business hours.” Subsection 245.730(b)(1) of the Rules states, in the event of an emergency, that a health professional may call the Department during “normal business hours.” For an emergency that occurs after hours, the Rules suggest calling the trade secret holder. This is inadequate. The Department should provide a 24- hour hotline for emergency calls pursuant to this section. “Trade Secret Holder.” Subsection 245.730(b)(2) of the Rules allows a health professional to seek the necessary information from a “trade secret holder,” but there is no means provided for the health professional to know who the trade secret holder is, or what phone number to use to reach it. Furthermore, this provision is found nowhere in the statute, seemingly adding another unnecessary burden on the health professional. Lack of a time limit for the Department’s response. The Department should abide by the same 3-hour time limit for a response that applies to trade secret holders pursuant to 245.730(b)(2). Disclosure of names receiving trade secret information. Subsection 245.730(e) of the rules requires that health providers report to the trade secret holder the names of persons to whom the protected information was disclosed. This requirement is found nowhere in the statute. It is inappropriate to burden health professionals with such an obligation in the absence of statutory authorization to do so. Revisions Needed: Rewrite the section to comply with the strongest interpretation of 1-77 of the Statute including 24-hour accessibility. This is inadequate. The Department should provide a 24- hour hotline for emergency calls pursuant to this section. “Trade Secret Holder.” Subsection 245.730(b)(2) of the Rules allows a health professional to seek the necessary information from a “trade secret holder,” but there is no means provided for the health professional to know who the trade secret holder is, or what phone number to use to reach it. Furthermore, this provision is found nowhere in the statute, seemingly adding another unnecessary burden on the health professional. Lack of a time limit for the Department’s response. The Department should abide by the same 3-hour time limit for a response that applies to trade secret holders pursuant to 245.730(b)(2). Disclosure of names receiving trade secret information. Subsection 245.730(e) of the rules requires that health providers report to the trade secret holder the names of persons to whom the protected information was disclosed. This requirement is found nowhere in the statute. It is inappropriate to burden health professionals with such an obligation in the absence of statutory authorization to do so. Revisions Needed: Rewrite the section to comply with the strongest interpretation of 1-77 of the Statute including 24-hour accessibility. Do not require that health providers report names of persons to whom protected information was disclosed as this was not required in the statute.

Sincerely, Paloma Delgadillo Plano, IL 75075

### Section 245.730 Trade Secret Disclosure to Health Professional

The proposed language concerning disclosure of trade secret-protected information to health professionals is neither consistent with the statute nor protective of the public. Right to Know. Section 1-77(l) of the Act is clear that information shall be provided, as needed, to health professionals who demonstrate a need for it. Yet, section 245.730 of the Rules diminishes the language of the Act, stating only that the Department “may” provide information to health professionals who demonstrate a need for it. Limitation to “normal business hours.” Subsection 245.730(b)(1) of the Rules states, in the event of an emergency, that a health professional may call the Department during “normal business hours.” For an emergency that occurs after hours, the Rules suggest calling the trade secret holder. This is inadequate. The Department should provide a 24- hour hotline for emergency calls pursuant to this section. “Trade Secret Holder.” Subsection 245.730(b)(2) of the Rules allows a health professional to seek the necessary information from a “trade secret holder,” but there is no means provided for the health professional to know who the trade secret holder is, or what phone number to use to reach it. Furthermore, this provision is found nowhere in the statute, seemingly adding another unnecessary burden on the health professional. Lack of a time limit for the Department’s response. The Department should abide by the same 3-hour time limit for a response that applies to trade secret holders pursuant to 245.730(b)(2). Disclosure of names receiving trade secret information. Subsection 245.730(e) of the rules requires that health providers report to the trade secret holder the names of persons to whom the protected information was disclosed. This requirement is found nowhere in the statute. It is inappropriate to burden health professionals with such an obligation in the absence of statutory authorization to do so. Revisions Needed: Rewrite the section to comply with the strongest interpretation of 1-77 of the Statute including 24-hour accessibility. This is inadequate. The Department should provide a 24- hour hotline for emergency calls pursuant to this section. “Trade Secret Holder.” Subsection 245.730(b)(2) of the Rules allows a health professional to seek the necessary information from a “trade secret holder,” but there is no means provided for the health professional to know who the trade secret holder is, or what phone number to use to reach it. Furthermore, this provision is found nowhere in the statute, seemingly adding another unnecessary burden on the health professional. Lack of a time limit for the Department’s response. The Department should abide by the same 3-hour time limit for a response that applies to trade secret holders pursuant to 245.730(b)(2). Disclosure of names receiving trade secret information. Subsection 245.730(e) of the rules requires that health providers report to the trade secret holder the names of persons to whom the protected information was disclosed. This requirement is found nowhere in the statute. It is inappropriate to burden health professionals with such an obligation in the absence of statutory authorization to do so. Revisions Needed: Rewrite the section to comply with the strongest interpretation of 1-77 of the Statute including 24-hour accessibility. Do not require that health providers report names of persons to whom protected information was disclosed as this was not required in the statute.

Sincerely, Rachelle Ankney Chicago, IL 60626

### Section 245.730 Trade Secret Disclosure to Health Professional

The proposed language concerning disclosure of trade secret-protected information to health professionals is neither consistent with the statute nor protective of the public. Right to Know. Section 1-77(l) of the Act is clear that information shall be provided, as needed, to health professionals who demonstrate a need for it. Yet, section 245.730 of the Rules diminishes the language of the Act, stating only that the Department “may” provide information to health professionals who demonstrate a need for it. Limitation to “normal business hours.” Subsection 245.730(b)(1) of the Rules states, in the event of an emergency, that a health professional may call the Department during “normal business hours.” For an emergency that occurs after hours, the Rules suggest calling the trade secret holder. This is inadequate. The Department should provide a 24- hour hotline for emergency calls pursuant to this section. “Trade Secret Holder.” Subsection 245.730(b)(2) of the Rules allows a health professional to seek the necessary information from a “trade secret holder,” but there is no means provided for the health professional to know who the trade secret holder is, or what phone number to use to reach it. Furthermore, this provision is found nowhere in the statute, seemingly adding another unnecessary burden on the health professional. Lack of a time limit for the Department’s response. The Department should abide by the same 3-hour time limit for a response that applies to trade secret holders pursuant to 245.730(b)(2). Disclosure of names receiving trade secret information. Subsection 245.730(e) of the rules requires that health providers report to the trade secret holder the names of persons to whom the protected information was disclosed. This requirement is found nowhere in the statute. It is inappropriate to burden health professionals with such an obligation in the absence of statutory authorization to do so. Revisions Needed: Rewrite the section to comply with the strongest interpretation of 1-77 of the Statute including 24-hour accessibility. Do not require that health providers report names of persons to whom protected information was disclosed as this was not required in the statute.

This is inadequate. The Department should provide a 24- hour hotline for emergency calls pursuant to this section. “Trade Secret Holder.” Subsection 245.730(b)(2) of the Rules allows a health professional to seek the necessary information from a “trade secret holder,” but there is no means provided for the health professional to know who the trade secret holder is, or what phone number to use to reach it. Furthermore, this provision is found nowhere in the statute, seemingly adding another unnecessary burden on the health professional. Lack of a time limit for the Department’s response. The Department should abide by the same 3-hour time limit for a response that applies to trade secret holders pursuant to 245.730(b)(2). Disclosure of names receiving trade secret information. Subsection 245.730(e) of the rules requires that health providers report to the trade secret holder the names of persons to whom the protected information was disclosed. This requirement is found nowhere in the statute. It is inappropriate to burden health professionals with such an obligation in the absence of statutory authorization to do so. Revisions Needed: Rewrite the section to comply with the strongest interpretation of 1-77 of the Statute including 24-hour accessibility. Do not require that health providers report names of persons to whom protected information was disclosed as this was not required in the statute.

Sincerely, Roderick Luke Chan Chicago, IL 60615

### Section 245.730 Trade Secret Disclosure to Health Professional

The proposed language concerning disclosure of trade secret-protected information to health professionals is neither consistent with the statute nor protective of the public. Right to Know. Section 1-77(l) of the Act is clear that information shall be provided, as needed, to health professionals who demonstrate a need for it. Yet, section 245.730 of the Rules diminishes the language of the Act, stating only that the Department “may” provide information to health professionals who demonstrate a need for it. Limitation to “normal business hours.” Subsection 245.730(b)(1) of the Rules states, in the event of an emergency, that a health professional may call the Department during “normal business hours.” For an emergency that occurs after hours, the Rules suggest calling the trade secret holder. This is inadequate. The Department should provide a 24- hour hotline for emergency calls pursuant to this section. “Trade Secret Holder.” Subsection 245.730(b)(2) of the Rules allows a health professional to seek the necessary information from a “trade secret holder,” but there is no means provided for the health professional to know who the trade secret holder is, or what phone number to use to reach it. Furthermore, this provision is found nowhere in the statute, seemingly adding another unnecessary burden on the health professional. Lack of a time limit for the Department’s response. The Department should abide by the same 3-hour time limit for a response that applies to trade secret holders pursuant to 245.730(b)(2). Disclosure of names receiving trade secret information. Subsection 245.730(e) of the rules requires that health providers report to the trade secret holder the names of persons to whom the protected information was disclosed. This requirement is found nowhere in the statute. It is inappropriate to burden health professionals with such an obligation in the absence of statutory authorization to do so. Revisions Needed: Rewrite the section to comply with the strongest interpretation of 1-77 of the Statute including 24-hour accessibility. Do not require that health providers report names of persons to whom protected information was disclosed as this was not required in the statute.

This is inadequate. The Department should provide a 24- hour hotline for emergency calls pursuant to this section. “Trade Secret Holder.” Subsection 245.730(b)(2) of the Rules allows a health professional to seek the necessary information from a “trade secret holder,” but there is no means provided for the health professional to know who the trade secret holder is, or what phone number to use to reach it. Furthermore, this provision is found nowhere in the statute, seemingly adding another unnecessary burden on the health professional. Lack of a time limit for the Department’s response. The Department should abide by the same 3-hour time limit for a response that applies to trade secret holders pursuant to 245.730(b)(2). Disclosure of names receiving trade secret information. Subsection 245.730(e) of the rules requires that health providers report to the trade secret holder the names of persons to whom the protected information was disclosed. This requirement is found nowhere in the statute. It is inappropriate to burden health professionals with such an obligation in the absence of statutory authorization to do so. Revisions Needed: Rewrite the section to comply with the strongest interpretation of 1-77 of the Statute including 24-hour accessibility. Do not require that health providers report names of persons to whom protected information was disclosed as this was not required in the statute.

Sincerely, Shaden Amara Naperville, IL 60564

### Section 245.730 Trade Secret Disclosure to Health Professional

The proposed language concerning disclosure of trade secret-protected information to health professionals is neither consistent with the statute nor protective of the public. Right to Know. Section 1-77(l) of the Act is clear that information shall be provided, as needed, to health professionals who demonstrate a need for it. Yet, section 245.730 of the Rules diminishes the language of the Act, stating only that the Department “may” provide information to health professionals who demonstrate a need for it. Limitation to “normal business hours.” Subsection 245.730(b)(1) of the Rules states, in the event of an emergency, that a health professional may call the Department during “normal business hours.” For an emergency that occurs after hours, the Rules suggest calling the trade secret holder. This is inadequate. The Department should provide a 24- hour hotline for emergency calls pursuant to this section. “Trade Secret Holder.” Subsection 245.730(b)(2) of the Rules allows a health professional to seek the necessary information from a “trade secret holder,” but there is no means provided for the health professional to know who the trade secret holder is, or what phone number to use to reach it. Furthermore, this provision is found nowhere in the statute, seemingly adding another unnecessary burden on the health professional. Lack of a time limit for the Department’s response. The Department should abide by the same 3-hour time limit for a response that applies to trade secret holders pursuant to 245.730(b)(2). Disclosure of names receiving trade secret information. Subsection 245.730(e) of the rules requires that health providers report to the trade secret holder the names of persons to whom the protected information was disclosed. This requirement is found nowhere in the statute. It is inappropriate to burden health professionals with such an obligation in the absence of statutory authorization to do so. Revisions Needed: Rewrite the section to comply with the strongest interpretation of 1-77 of the Statute including 24-hour accessibility. Do not require that health providers report names of persons to whom protected information was disclosed as this was not required in the statute.

This is inadequate. The Department should provide a 24- hour hotline for emergency calls pursuant to this section. “Trade Secret Holder.” Subsection 245.730(b)(2) of the Rules allows a health professional to seek the necessary information from a “trade secret holder,” but there is no means provided for the health professional to know who the trade secret holder is, or what phone number to use to reach it. Furthermore, this provision is found nowhere in the statute, seemingly adding another unnecessary burden on the health professional. Lack of a time limit for the Department’s response. The Department should abide by the same 3-hour time limit for a response that applies to trade secret holders pursuant to 245.730(b)(2). Disclosure of names receiving trade secret information. Subsection 245.730(e) of the rules requires that health providers report to the trade secret holder the names of persons to whom the protected information was disclosed. This requirement is found nowhere in the statute. It is inappropriate to burden health professionals with such an obligation in the absence of statutory authorization to do so. Revisions Needed: Rewrite the section to comply with the strongest interpretation of 1-77 of the Statute including 24-hour accessibility. Do not require that health providers report names of persons to whom protected information was disclosed as this was not required in the statute.

Sincerely, Tim Dompke Collinsville, IL 62224

### Section 245.730 Trade Secret Disclosure to Health Professional

The proposed language concerning disclosure of trade secret-protected information to health professionals is neither consistent with the statute nor protective of the public. Right to Know. Section 1-77(l) of the Act is clear that information shall be provided, as needed, to health professionals who demonstrate a need for it. Yet, section 245.730 of the Rules diminishes the language of the Act, stating only that the Department “may” provide information to health professionals who demonstrate a need for it. Limitation to “normal business hours.” Subsection 245.730(b)(1) of the Rules states, in the event of an emergency, that a health professional may call the Department during “normal business hours.” For an emergency that occurs after hours, the Rules suggest calling the trade secret holder. This is inadequate. The Department should provide a 24- hour hotline for emergency calls pursuant to this section. “Trade Secret Holder.” Subsection 245.730(b)(2) of the Rules allows a health professional to seek the necessary information from a “trade secret holder,” but there is no means provided for the health professional to know who the trade secret holder is, or what phone number to use to reach it. Furthermore, this provision is found nowhere in the statute, seemingly adding another unnecessary burden on the health professional. Lack of a time limit for the Department’s response. The Department should abide by the same 3-hour time limit for a response that applies to trade secret holders pursuant to 245.730(b)(2). Disclosure of names receiving trade secret information. Subsection 245.730(e) of the rules requires that health providers report to the trade secret holder the names of persons to whom the protected information was disclosed. This requirement is found nowhere in the statute. It is inappropriate to burden health professionals with such an obligation in the absence of statutory authorization to do so. Revisions Needed: Rewrite the section to comply with the strongest interpretation of 1-77 of the Statute including 24-hour accessibility. Do not require that health providers report names of persons to whom protected information was disclosed as this was not required in the statute.

This is inadequate. The Department should provide a 24- hour hotline for emergency calls pursuant to this section. “Trade Secret Holder.” Subsection 245.730(b)(2) of the Rules allows a health professional to seek the necessary information from a “trade secret holder,” but there is no means provided for the health professional to know who the trade secret holder is, or what phone number to use to reach it. Furthermore, this provision is found nowhere in the statute, seemingly adding another unnecessary burden on the health professional. Lack of a time limit for the Department’s response. The Department should abide by the same 3-hour time limit for a response that applies to trade secret holders pursuant to 245.730(b)(2). Disclosure of names receiving trade secret information. Subsection 245.730(e) of the rules requires that health providers report to the trade secret holder the names of persons to whom the protected information was disclosed. This requirement is found nowhere in the statute. It is inappropriate to burden health professionals with such an obligation in the absence of statutory authorization to do so. Revisions Needed: Rewrite the section to comply with the strongest interpretation of 1-77 of the Statute including 24-hour accessibility. Do not require that health providers report names of persons to whom protected information was disclosed as this was not required in the statute.

Sincerely, Virginia Baker Chicago, IL 60608

### Section 245.730 Trade Secret Disclosure to Health Professional

The proposed language concerning disclosure of trade secret-protected information to health professionals is neither consistent with the statute nor protective of the public. Right to Know. Section 1-77(l) of the Act is clear that information shall be provided, as needed, to health professionals who demonstrate a need for it. Yet, section 245.730 of the Rules diminishes the language of the Act, stating only that the Department “may” provide information to health professionals who demonstrate a need for it. Limitation to “normal business hours.” Subsection 245.730(b)(1) of the Rules states, in the event of an emergency, that a health professional may call the Department during “normal business hours.” For an emergency that occurs after hours, the Rules suggest calling the trade secret holder. This is inadequate. The Department should provide a 24- hour hotline for emergency calls pursuant to this section. “Trade Secret Holder.” Subsection 245.730(b)(2) of the Rules allows a health professional to seek the necessary information from a “trade secret holder,” but there is no means provided for the health professional to know who the trade secret holder is, or what phone number to use to reach it. Furthermore, this provision is found nowhere in the statute, seemingly adding another unnecessary burden on the health professional. Lack of a time limit for the Department’s response. The Department should abide by the same 3-hour time limit for a response that applies to trade secret holders pursuant to 245.730(b)(2). Disclosure of names receiving trade secret information. Subsection 245.730(e) of the rules requires that health providers report to the trade secret holder the names of persons to whom the protected information was disclosed. This requirement is found nowhere in the statute. It is inappropriate to burden health professionals with such an obligation in the absence of statutory authorization to do so. Revisions Needed: Rewrite the section to comply with the strongest interpretation of 1-77 of the Statute including 24-hour accessibility. Do not require that health providers report names of persons to whom protected information was disclosed as this was not required in the statute.

### Section 245.730 Trade Secret Disclosure to Health Professional

The proposed use of water and the right to irrevocably pollute our water system is a form of genocide. It is nonsensical for any corporation to be exempt from the clean air and clean water acts; the proposed penalties for violating the inadequate regulations that exist are so low as to be laughable; giving away enormous amounts of water to be forever poisoned in the middle of a drought is an act that is so ridiculous as to be difficult to comprehend; the refusal to disclose the chemicals involved in fracturing poses an irretrievable risk to public health and safety; cost to the state in road maintenance will outstrip revenue by 2-3 times. Please stop this insanity. Don't exchange the ability for humans to healthfully subsist in our region for the financial profit of a very few. Please do your duty and protect the health and well being of Southern Illinois, and do not allow fracking. It cannot be made safe, and regulations are a deceiving pretense.

Sincerely, Priscilla Pimentel Carbondale, IL 62901

### Section 245.730 Trade Secret Disclosure to Health Professional

To the IDNR on proposed fracking administrative rules: Please note that I do not believe fracking is safe or can be made safe and I support at minimum a moratorium on fracking in Illinois, and better still, an outright ban. The proposed administrative rules you've written are inadequate on so many levels for protecting the environment and the people of Illinois, but I will specifically call attention to these items: -inconsequential fines for serious violations of safety (section 245-1120)--the oil and gas industry is likely in the top five money making industries in this nation, but your proposed fines are from \$50 to \$2500. The damage fracking will do to the public health and environment will cost taxpayers and the state far more than you'll ever recoup from the oil and gas industry. Increase these fines so safety is taken seriously. -water quality-section 245.600 indicates water quality testing would only need to occur within 1500 ft of a well. Are you familiar with how groundwater is contaminated at all? The water quality needs to be tested well beyond 1500 ft. --water usage. We will see serious water shortages, particularly in drought conditions, due to the huge amounts of water that fracking requires. yet section 245.210 makes no requirement for fracking companies to apply to local government for use of ground or surface water. Overall, it seems clear you've not written these rules with science or public health authorities guidance at all. Please take considerable time to re-write these rules. The citizens of Illinois at least need you to take the regulation of this travesty seriously.

Sincerely, Jesslyn Jobe 1111 W. Walkup Ave. Carbondale, IL 62901

### Section 245.730 Trade Secret Disclosure to Health Professional

To the Illinois Department of Natural Resources, My name is Rebecca Quesnell and I have been an Illinois resident for several years now. I am also an individual who extremely passionate about the environment and I find peoples' ultimate dependence on it to be astonishing. That is why I am extremely concerned with multiple inadequacies in the proposed rules and regulations. The main one that I am addressing right now is with regards to the disclosure of trade secret-protected information to health professionals. I find it to be extremely inconsistent and it fails to protect the public in the area surrounding fracking operations. The following is language that is inconsistent and, further, inadequacies with regards to chemical disclosure: Right to Know. Section 1-77(l) of the Act is clear that information shall be provided, as needed, to health professionals who demonstrate a need for it. However, section 245.730 of the Rules diminishes the language of the Act by stating only that the Department "may" provide information to health professionals who demonstrate a need for it. Shall be provided, as needed, and may provide it is inconsistent. The term "may" makes it seem that these companies/ trade secret holders do not need to release the information to health care professionals unless they want to. Limitation to "normal business hours." Subsection 245.730(b)(1) of the Rules states that, in the event of an emergency, a health professional may call the Department during "normal business hours." However, for an emergency that occurs after hours, the Rules suggest calling the trade secret holder. This is extremely inadequate and does not make sense at all! The Department should, and needs to, provide a 24-hour hotline for emergency calls pursuant to this section. This also leads into the fact that health professionals have no way of knowing who the trade secret holder may be... "Trade Secret Holder." Subsection 245.730(b)(2) of the Rules allows a health professional to seek the necessary information from a "trade secret holder," but there is no means provided for the health professional to know who the trade secret holder is, or what phone number to use to reach the trade secret holder. Additionally, this provision is found nowhere in the statute, seemingly adding another unnecessary burden on the health professional as well as making it harder for them to do their job and help someone in the event of an emergency! Lack of a time limit for the Department's response. The Department should abide by the same 3-hour time limit for a response that applies to trade secret holders pursuant to 245.730(b)(2). Disclosure of names receiving trade secret information. Subsection 245.730(e) of the rules requires that health providers report to the trade secret holder the names of persons to whom the protected information was disclosed. This requirement is found nowhere in the statute. It is inappropriate to burden health professionals with such an obligation in the absence of statutory authorization to do so. Due to these inadequacies that are apparent, burden health care professionals, and do not even attempt to protect/ help the public, I feel that this section greatly needs to be improved upon and should be rewritten. I suggest rewriting the section in order to comply with the strongest interpretation of 1-77 of the Statute including 24-hour accessibility. I also demand that you do not require that health providers report names of persons to whom protected information was disclosed as this was not required in the statute. Ultimately, this section is terribly structured and written and due to

## Fair Economy Illinois

---

some of the language used, it also creates loopholes for these companies so that they can avoid addressing issues appropriately and reasonably as well as increase their profits in the end. Who's side are you on IDNR? If anything you should at least be a neutral party writing these rules and regulations but it is apparent that you are not working to protect potentially affected parties of people in the area, and you certainly not protecting the environment! Get your heads on straight and start doing your job, please and thank you. And thank you for taking the time to read this and, ultimately, thank you in advance address these concerns that I am putting before you.

Sincerely, Rebecca Quesnell 3 Talisman Trace Galena, IL 61036

This section lacks the specificity needed to insure that fracking will be conducted in a manner that will protect the public health and safety and prevent pollution or diminution of any water source. (Statute 1-53(4)) "Compatible" (245.825(a)(2), (c)(1)). The regulations should clarify what is "compatible" for purposes of provisions that tanks and "piping, conveyances, ... must be constructed of materials compatible with the composition of the fracking fluid...." Specifically, the Department should clarify that "compatible" includes being resistant to corrosion, erosion, swelling, or degradation that may result from such contact. Corrosion inspection (245.825(a)(5)). The Department should define what is meant by the requirement that above-ground tanks be "routinely" inspected for corrosion, i.e., specify a time interval. Secondary containment (245.825(b)). The Department should require that secondary containment be designed and constructed in accordance with good engineering practices, including: (a) Using coated or lined materials that are chemically compatible with the environment and the substances to be contained; (b) Providing adequate freeboard; (c) Protecting containment from heavy vehicle or equipment traffic.

Sincerely, Alicia Klepfer Chicago, IL 60615

Corrosion inspection (245.825(a)(5)). The Department should define what is meant by the requirement that above-ground tanks be "routinely" inspected for corrosion, i.e., specify a time interval. Secondary containment (245.825(b)). The Department should require that secondary containment be designed and constructed in accordance with good engineering practices, including: (a) Using coated or lined materials that are chemically compatible with the environment and the substances to be contained; (b) Providing adequate freeboard; (c) Protecting containment from heavy vehicle or equipment traffic.

Sincerely, Bob Venier Dixon, IL 61021

### Section 245.825 General Fluid Storage

This section lacks the specificity needed to insure that fracking will be conducted in a manner that will protect the public health and safety and prevent pollution or diminution of any water source. (Statute 1-53(4)) "Compatible" (245.825(a)(2), (c)(1)). The regulations should clarify what is "compatible" for purposes of provisions that tanks and "piping, conveyances, ... must be constructed of materials compatible with the composition of the fracking fluid...." Specifically, the Department should clarify that "compatible" includes being resistant to corrosion, erosion, swelling, or degradation that may result from such contact. Corrosion inspection (245.825(a)(5)). The Department should define what is meant by the requirement that above-ground tanks be "routinely" inspected for corrosion, i.e., specify a time interval. Secondary containment (245.825(b)). The Department should require that secondary containment be designed and constructed in accordance with good engineering practices, including: (a) Using coated or lined materials that are chemically compatible with the environment and the substances to be contained; (b) Providing adequate freeboard; (c) Protecting containment from heavy vehicle or equipment traffic.

This section lacks the specificity needed to insure that fracking will be conducted in a manner that will protect the public health and safety and prevent pollution or diminution of any water source. (Statute 1-53(4)) "Compatible" (245.825(a)(2), (c)(1)). The regulations should clarify what is "compatible" for purposes of provisions that tanks and "piping, conveyances, ... must be constructed of materials compatible with the composition of the fracking fluid...." Specifically, the Department should clarify that "compatible" includes being resistant to corrosion, erosion, swelling, or degradation that may result from such contact. Corrosion inspection (245.825(a)(5)). The Department should define what is meant by the requirement that above-ground tanks be "routinely" inspected for corrosion, i.e., specify a time interval. Secondary containment (245.825(b)). The Department should require that secondary containment be designed and constructed in accordance with good engineering practices, including: (a) Using coated or lined materials that are chemically compatible with the environment and the substances to be contained; (b) Providing adequate freeboard; (c) Protecting containment from heavy vehicle or equipment traffic.

Sincerely, Emerson Delgado Chicago, IL 60637

### Section 245.825 General Fluid Storage

This section lacks the specificity needed to insure that fracking will be conducted in a manner that will protect the public health and safety and prevent pollution or diminution of any water source. (Statute 1-53(4)) "Compatible" (245.825(a)(2), (c)(1)). The regulations should clarify what is "compatible" for purposes of provisions that tanks and "piping, conveyances, ... must be constructed of materials compatible with the composition of the fracking fluid...." Specifically, the Department should clarify that "compatible" includes being resistant to corrosion, erosion, swelling, or degradation that may result from such contact. Corrosion inspection (245.825(a)(5)). The Department should define what is meant by the requirement that above-ground tanks be "routinely" inspected for corrosion, i.e., specify a time interval. Secondary containment (245.825(b)). The Department should require that secondary containment be designed and constructed in accordance with good engineering practices, including: (a) Using coated or lined materials that are chemically compatible with the environment and the substances to be contained; (b) Providing adequate freeboard; (c) Protecting containment from heavy vehicle or equipment traffic.

The regulations should clarify what is "compatible" for purposes of provisions that tanks and "piping, conveyances, ... must be constructed of materials compatible with the composition of the fracking fluid...." Specifically, the Department should clarify that "compatible" includes being resistant to corrosion, erosion, swelling, or degradation that may result from such contact. Corrosion inspection (245.825(a)(5)). The Department should define what is meant by the requirement that above-ground tanks be "routinely" inspected for corrosion, i.e., specify a time interval. Secondary containment (245.825(b)). The Department should require that secondary containment be designed and constructed in accordance with good engineering practices, including: (a) Using coated or lined materials that are chemically compatible with the environment and the substances to be contained; (b) Providing adequate freeboard; (c) Protecting containment from heavy vehicle or equipment traffic.

Sincerely, Kathy Machaj Chicago, IL 60607

### Section 245.825 General Fluid Storage

This section lacks the specificity needed to insure that fracking will be conducted in a manner that will protect the public health and safety and prevent pollution or diminution of any water source. (Statute 1-53(4)) "Compatible" (245.825(a)(2), (c)(1)). The regulations should clarify what is "compatible" for purposes of provisions that tanks and "piping, conveyances, ... must be constructed of materials compatible with the composition of the fracking fluid...." Specifically, the Department should clarify that "compatible" includes being resistant to corrosion, erosion, swelling, or degradation that may result from such contact. Corrosion inspection (245.825(a)(5)). The Department should define what is meant by the requirement that above-ground tanks be "routinely" inspected for corrosion, i.e., specify a time interval. Secondary containment (245.825(b)). The Department should require that secondary containment be designed and constructed in accordance with good engineering practices, including: (a) Using coated or lined materials that are chemically compatible with the environment and the substances to be contained; (b) Providing adequate freeboard; (c) Protecting containment from heavy vehicle or equipment traffic.

Sincerely, Maheema Haque Chicago, IL 60637

Corrosion inspection (245.825(a)(5)). The Department should define what is meant by the requirement that above-ground tanks be "routinely" inspected for corrosion, i.e., specify a time interval. Secondary containment (245.825(b)). The Department should require that secondary containment be designed and constructed in accordance with good engineering practices, including: (a) Using coated or lined materials that are chemically compatible with the environment and the substances to be contained; (b) Providing adequate freeboard; (c) Protecting containment from heavy vehicle or equipment traffic.

Sincerely, Paul Kim Chicago, IL 60637

### Section 245.825 General Fluid Storage

This section lacks the specificity needed to insure that fracking will be conducted in a manner that will protect the public health and safety and prevent pollution or diminution of any water source. (Statute 1-53(4)) "Compatible" (245.825(a)(2), (c)(1)). The regulations should clarify what is "compatible" for purposes of provisions that tanks and "piping, conveyances, ... must be constructed of materials compatible with the composition of the fracking fluid...." Specifically, the Department should clarify that "compatible" includes being resistant to corrosion, erosion, swelling, or degradation that may result from such contact. Corrosion inspection (245.825(a)(5)). The Department should define what is meant by the requirement that above-ground tanks be "routinely" inspected for corrosion, i.e., specify a time interval. Secondary containment (245.825(b)). The Department should require that secondary containment be designed and constructed in accordance with good engineering practices, including: (a) Using coated or lined materials that are chemically compatible with the environment and the substances to be contained; (b) Providing adequate freeboard; (c) Protecting containment from heavy vehicle or equipment traffic.

### Section 245.825 General Fluid Storage

This section lacks the specificity needed to insure that fracking will be conducted in a manner that will protect the public health and safety and prevent pollution or diminution of any water source. (Statute 1-53(4)) "Compatible" (245.825(a)(2), (c)(1)). The regulations should clarify what is "compatible" for purposes of provisions that tanks and "piping, conveyances, ... must be constructed of materials compatible with the composition of the fracking fluid...." Specifically, the Department should clarify that "compatible" includes being resistant to corrosion, erosion, swelling, or degradation that may result from such contact. Corrosion inspection (245.825(a)(5)). The Department should define what is meant by the requirement that above-ground tanks be "routinely" inspected for corrosion, i.e., specify a time interval. Secondary containment (245.825(b)). The Department should require that secondary containment be designed and constructed in accordance with good engineering practices, including: (a) Using coated or lined materials that are chemically compatible with the environment and the substances to be contained; (b) Providing adequate freeboard; (c) Protecting containment from heavy vehicle or equipment traffic.

Sincerely, Sophia Johnson Chicago, IL 60605

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Section 1-75 of the Hydraulic Fracturing Regulator Act mandates that “excess hydraulic fracturing flowback captured for temporary storage in a reserve pit as provided in paragraph (2) of this subsection must be removed from the well site within 7 days.” But Section 245.850 of the proposed rules states, “Any excess hydraulic fracturing flowback captured for temporary storage in a reserve pit as provided in Section 245.825 must be removed from the well site or transferred to storage in above-ground tanks for later disposal or recycling within 7 days after completion of high volume horizontal hydraulic fracturing operations.” Problem: The amendment of “after completion of high volume horizontal hydraulic fracturing operations” opens the door for the potential abuse of emergency pits. Storage in closed tanks can be costly for the industry. An unscrupulous operator wanting to cut costs could simply claim that there was more flowback than expected and end up using open pits for storage for the duration of the fracking process. The clear intent of the statute is to ensure that wastewater is stored in tanks except in the emergency event of an unforeseeable overflow, in which case it is preferable that the overflow go to a pit than simply spill on the ground. But in such event, the overflow is expressly required in the statute to be removed within a week. Through omission and misinterpretation, the regulations are not implementing this statutory directive. Section 245.210(a)(11), requires that an applicant submit a Hydraulic Fracturing Fluids and Flowback Plan. The plan does not include requirements to ensure that tank capacity is accurately calculated. Without such method, there is nothing in the regulations to prevent operators from underestimating the size of the tanks they need, so as to make routine use of the reserve pit for the resulting overflows. Operators presumably have an economic incentive to do so in order to hold down the cost of tank storage. Compounding this incentive is the Department’s weakening of the statutory directive that fluids deposited in a reserve pit be removed within 7 days (Section 1-75(c)(5)). The regulations fail to require such prompt removal, allowing, at subsection 245.850(c), the overflow to remain in the reserve pits until 7 days “after completion of high volume horizontal hydraulic fracturing operations.” Certainly on a multi-well pad, hydraulic fracturing operations can continue for a month or more, meaning that the flowback fluid could be left sitting in the reserve pit, creating environmental risk, for much longer than a week. Revisions needed: First, require that drillers anticipate appropriate sized tanks for sufficient storage of flowback and produced water by establishing a method for tank capacity calculation. Second, clarify that wastewater must be removed from the pit within 7 days of the event that triggered the use of the pit rather than 7 days after fracking operations are complete, in accordance with the law.

Sincerely, B. E. Murphy 458 Tahoe Park Forest, IL 60466

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

A woman who was very influential to my life passed away 3 years ago from cancer. Her doctor explained to us that the cause of her cancer must have been environmental since she was still rather young, only being middle aged. The most likely cause, the doctor explained, was the year that she spent living in a very polluted region of Egypt. As the government lacked proper regulation and enforcement of the pollution of the area and storage of waste, many carcinogens and electronic waste ended up in the environment where people and families spent their time. This woman was very close to me and was the sole caretaker of five children. After she died, it has been extremely difficult on her children, family, and friends. It is heartbreaking that many moments, such as the high school graduation of three of the children and her sons engagement, would have to happen without her presence. This experience has been heartbreaking. If having stronger rules on the storage and testing of wastewater could just help the health of one person, then it will be worth it. Comment/Problem(s)/Needed Revisions: Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Notably absent from these proposed rules is a requirement for the testing of "produced water", the fluid that returns from the well during the later stage of production (after flowback). Under the proposed rules, "produced water" can be stored on site and/or can be "recycled", yet there is no testing requirement. Naturally occurring radioactive material (NORM) is found in "produced water" also. See Technologically enhanced naturally occurring radioactive materials in the oil industry (TENORM), Nukleonika 2009; 54(1):3-9, and sources cited therein, especially for TENORM in produced water in the U.S., available at [http://www.nukleonika.pl/www/back/full/vol54\\_2009/v54n1p003f.pdf](http://www.nukleonika.pl/www/back/full/vol54_2009/v54n1p003f.pdf). See also NORM is also found on scale in oil pipes and on fracking equipment. (See Kentucky Resources Council Proposes Comprehensive Plan For Investigating Radiological Contamination In Martha Oil Field. August 11, 2005. <http://www.kyrc.org/webnewspro/112381723236086.shtml>.) IDNR's definitions of "flowback water" and "produced water" are different. The two are distinguishably different enough that they are treated as separate types of fluid by both the Hydraulic Fracturing Regulatory Act and by the DNR Rules. Discharge of produced water onto the ground or into surface water or water drainage way is prohibited but it is not tested for radioactivity. This despite the fact that this fluid will be in contact with the naturally occurring radioactive elements in the ground for a longer period that the flowback and that it is much more likely to be radioactive. Problems: Failure to test produced water for radioactivity is problematic for a variety of reasons including: The health and safety of workers on the site who will be unaware of the levels of radioactivity they are being exposed to. The health and safety of workers transporting produced water who will also be in the dark regarding the levels of radioactivity they will be exposed to. The risk of storing radioactive material in tanks not created for storing radioactive materials. The risk of "recycling" produced water—radioactivity cannot be removed by recycling. The risk to the public in transporting radioactive materials Argonne National Laboratory recently cautioned

## Fair Economy Illinois

---

about radiological doses: "It is commonly accepted that efforts should be undertaken at all times to keep radiological doses 'as low as reasonably achievable,' which is referred to as the ALARA principle or requirement." Overview of Radiological Dose and Risk Assessment (April 2011). DNR is failing to even adequately test for radioactivity and therefore, will not know the levels of radioactivity. How, then, can DNR adequately protect workers and the general public? Revisions needed: At a bare minimum, the rules should require that "produced water" be tested at two separate intervals across time for radioactivity. This is already required in Pennsylvania. The rules should also require that the requirements of the Illinois Low Level Radioactivity Waste Management Act be followed.

Sincerely, Harry Li 2656 Boddington Lane Naperville, IL 60564

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Act §1-75(a)7 requires radioactivity testing "once per well site" for (1) flowback water and ground "adjacent to" (2) storage tanks and (3) reserve pits. Act § 1-120 requires IDNR compliance with all "applicable federal, State, and local laws." One applicable State law is the Illinois Low-Level Radioactive Waste Management Act (PA 83-991 / 420ILCS20). Another is the Occupational Health and Safety Administration (OSHA) standards for workplace safety in settings with exposure to radioactivity (29 CFR 1910.1096). Rules §245.850(d)1-E and §245.850(e) are incomplete and deficient, and these inadequacies can "constitute a serious threat"--indeed, deadly threat-- "to the public interest, safety, or welfare" of Illinois citizens." Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Notably absent from these proposed rules is a requirement for the testing of "produced water", the fluid that returns from the well during the later stage of production (after flowback). Under the proposed rules, "produced water" can be stored on site and/or can be "recycled", yet there is no testing requirement. Naturally occurring radioactive material (NORM) is found in "produced water" also. DNR adequately protect workers and the general public? Elaboration: IDNR does not define a Fixed Date ( $\pm X$  days) for testing. Day 1, <Hour 1 test results will be orders of magnitude lower than either Day 2 or Day 10 tests results, and Day 10 tests results will be significantly lower than Day 80 ( $\pm 7$  days) results. Failure to specify a Fixed Test Date ( $\pm X$  days) renders test data so many irrelevant apples and oranges and allows companies to report suppressed, meaningless results by reporting Day 1, < 1 Hour data. The figure below, provided by the USGS, illustrates the nature of the problem. Please note that radium is not tested at Day 1, < 1 Hour. However, radium coprecipitates with barium, which is represented in total dissolved solids (TDS). It will therefore track TDS fairly closely. Conclusion: companies will be testing the very first flowback water to emerge from a fracked well. It will be Day 1, Minute 1 test results. 2.) There are two pits on a frack pad, one for "emergency" flowback and another, smaller one for drill cuttings and drilling mud. It is a basic principle in horizontal fracking to steer the drill bit through the horizontal strata with the highest gamma radiation readings (GAPI logs). The reason is that radioactivity correlates highly with total organic content (TOC) in the rock, and TOC correlates highly with oil and gas yields. This means that rock cuttings in the smaller drill mud and cuttings frack pit will often be more radioactive than flowback water. The IDNR knows this; yet it does not call for testing of drill bit pits as allowed under the Powers and duties section of the Act (§1- 15). 3.) The term "adjacent to" requires a "precise, clear standard" [IAPA, §100/5-20]. None is given. Does "adjacent to" mean 6 inches, 16 inches, 6 feet, 16 feet, or 60 feet? The IDNR does not say. 4.) Frack pad pipes and equipment can become incredibly radioactive over time. The very large temperature and pressure drops, as fluids move to the surface from thousands of feet underground, means that aqueous radioactive salts precipitate out as scale on pipes and equipment. The levels of radioactivity in pipe scale can exceed 100,000 picoCuries per gram and constitute a hazard to workers, or others who are exposed to recycled scrap metal from gas and oil operations. Yet, IDNR does not call on its General Assembly deferred "Power and authority" [Act, §1-15(e)] to test pipe, tanks, sludge, and equipment. This issue has been an issue in the oil and gas industry since the 1980s. Consequences: According to studies by the Illinois State Geological Survey, the Illinois New Albany Shale Formation, the source rock for our oil and gas reserves, has above average levels of uranium (29 ppm). Uranium decays into radium and thence radon. Both uranium and radium are water soluble. As noted, the U.S. Geological Survey has found oil field brine or produced water in Southern Illinois to have Radium226 levels that average more than 1,000 picoCuries / liter (USGS 1999). That reading is 67 times above the maximum contamination level of the EPA. Radium226 has a half life of 1,600 years. Uranium228 has a half life of 4.468 billion years. If these water soluble salts leach into our aquifers, nearby communities will require--if possible--very expensive water treatment for the next 1,000 years. We may have to return to rainwater harvesting with the modern equivalent of cisterns. The radioactive levels for produced water from shale gas operations are likely to be 2 to 4 times higher than oilfield brine -- on average, 2,000 to 4,000 picoCuries per liter. In addition, radon levels in methane, propane, and ethane can be dangerously high. When it becomes commercial to extract shale gas from the SE corner of the state, major markets, such as Springfield and Chicago, will only be 0.9 and 1.4 days removed from shale gas wellheads. Even though radon222 has a half life of only 3.8 days, the closeness of major Illinois retail gas markets will mean that large number of people will be breathing in high levels of radon when they cook meals. The average level of indoor exposure to radon in Illinois is already 4.4

## Fair Economy Illinois

---

pCi/L ( American Lung Association 2013). The EPA maximum level--the point at which corrective action should be taken--is 4.0 pCi/L, and the preferred level is =3.0 pCi/L. The turn to shale gas, with its high levels of radon, will also turn a major Illinois public health problem in the wrong direction. Radioactive scale in pipe and equipment presents another problem; high levels of radioactivity have been found in school playground equipment and bleachers in school sports stadiums in Mississippi and Texas. Do we want untested oil and gas field scrap metal sold into Illinois markets? Do we want our children exposed on a daily basis to radioactive metal? The present rules creates no barriers to such an outcome. The problems cited above are why Illinois, with its large number of nuclear power plants, has a Low-Level Radioactive Waste Management Act. It and OSHA are the applicable State and Federal agencies with respect to the issue of radioactive waste and work safety standards in settings with exposure to radioactivity. If we faithfully follow applicable State and federal laws, Illinois can minimize the pernicious problems other states are going to face from the uncontrolled release of radioactive elements into their water and soil and work and non-work settings. We should prevent these problem from the start. Cleanup, after the oil and gas industry is gone, will be dreadfully expensive.. Recommendations: 1. Define the test date as = Day 21, the point at which increases in test results begin to level off. 2. Test for "radioactivity" in (1) flowback/produced water, (2) drill cuttings, soil "adjacent to" (3) storage tanks and (4) reserve pits, and (5) pipes and well pad equipment. 3. Define "adjacent to" as between 6 and 12 inches with test samples to be taken within the top 6 inches of soil 4. The rules should also require that the requirements of the Illinois Low Level Radioactivity Waste Management Act be followed.

Sincerely, Abby Dompke Chicago, IL 60607

DNR adequately protect workers and the general public? Elaboration: IDNR does not define a Fixed Date ( $\pm X$  days) for testing. Day 1, <Hour 1 test results will be orders of magnitude lower than either Day 2 or Day 10 tests results, and Day 10 tests results will be significantly lower than Day 80 ( $\pm 7$  days) results. Failure to specify a Fixed Test Date ( $\pm X$  days) renders test data so many irrelevant apples and oranges and allows companies to report suppressed, meaningless results by reporting Day 1, < 1 Hour data. The figure below, provided by the USGS, illustrates the nature of the problem. Please note that radium is not tested at Day 1, < 1 Hour. However, radium coprecipitates with barium, which is represented in total dissolved solids (TDS). It will therefore track TDS fairly closely. Conclusion: companies will be testing the very first flowback water to emerge from a fracked well. It will be Day 1, Minute 1 test results. 2.) There are two pits on a frack pad, one for "emergency" flowback and another, smaller one for drill cuttings and drilling mud. It is a basic principle in horizontal fracking to steer the drill bit through the horizontal strata with the highest gamma radiation readings (GAPI logs). The reason is that radioactivity correlates highly with total organic content (TOC) in the rock, and TOC correlates highly with oil and gas yields. This means that rock cuttings in the smaller drill mud and cuttings frack pit will often be more radioactive than flowback water. The IDNR knows this; yet it does not call for testing of drill bit pits as allowed under the Powers and duties section of the Act (§1- 15). 3.) The term "adjacent to" requires a "precise, clear standard" [IAPA, §100/5-20]. None is given. Does "adjacent to" mean 6 inches, 16 inches, 6 feet, 16 feet, or 60 feet? The IDNR does not say. 4.) Frack pad pipes and equipment can become incredibly radioactive over time. The very large temperature and pressure drops, as fluids move to the surface from thousands of feet underground, means that aqueous radioactive salts precipitate out as scale on pipes and equipment. The levels of radioactivity in pipe scale can exceed 100,000 picoCuries per gram and constitute a hazard to workers, or others who are exposed to recycled scrap metal from gas and oil operations. Yet, IDNR does not call on its General Assembly deferred "Power and authority" [Act, §1-15(e)] to test pipe, tanks, sludge, and equipment. This issue has been an issue in the oil and gas industry since the 1980s. Consequences: According to studies by the Illinois State Geological Survey, the Illinois New Albany Shale Formation, the source rock for our oil and gas reserves, has above average levels of uranium (29 ppm). Uranium decays into radium and thence radon. Both uranium and radium are water soluble. As noted, the U.S. Geological Survey has found oil field brine or produced water in Southern Illinois to have Radium226 levels that average more than 1,000 picoCuries / liter (USGS 1999). That reading is 67 times above the maximum contamination level of the EPA. Radium226 has a half life of 1,600 years. Uranium228 has a half life of 4.468 billion years. If these water soluble salts leach into our aquifers, nearby communities will require--if possible--very expensive water treatment for the next 1,000 years. We may have to return to rainwater harvesting with the modern equivalent of cisterns. The radioactive levels for produced water from shale gas operations are likely to be 2 to 4 times higher than oilfield brine -- on average, 2,000 to 4,000 picoCuries per liter. In addition, radon levels in methane, propane, and ethane can be dangerously high. When it becomes commercial to extract shale gas from the SE corner of the state, major markets, such as Springfield and Chicago, will only be 0.9 and 1.4 days removed from shale gas wellheads. Even though radon222 has a half life of only 3.8 days, the closeness of major Illinois retail gas markets will mean that large number of people will be breathing in high levels of radon when they cook meals. The average level of indoor exposure to radon in Illinois is already 4.4

## Fair Economy Illinois

---

pCi/L ( American Lung Association 2013). The EPA maximum level--the point at which corrective action should be taken--is 4.0 pCi/L, and the preferred level is =3.0 pCi/L. The turn to shale gas, with its high levels of radon, will also turn a major Illinois public health problem in the wrong direction. Radioactive scale in pipe and equipment presents another problem; high levels of radioactivity have been found in school playground equipment and bleachers in school sports stadiums in Mississippi and Texas. Do we want untested oil and gas field scrap metal sold into Illinois markets? Do we want our children exposed on a daily basis to radioactive metal? The present rules creates no barriers to such an outcome. The problems cited above are why Illinois, with its large number of nuclear power plants, has a Low-Level Radioactive Waste Management Act. It and OSHA are the applicable State and Federal agencies with respect to the issue of radioactive waste and work safety standards in settings with exposure to radioactivity. If we faithfully follow applicable State and federal laws, Illinois can minimize the pernicious problems other states are going to face from the uncontrolled release of radioactive elements into their water and soil and work and non-work settings. We should prevent these problem from the start. Cleanup, after the oil and gas industry is gone, will be dreadfully expensive.. Recommendations: 1. Define the test date as = Day 21, the point at which increases in test results begin to level off. 2. Test for "radioactivity" in (1) flowback/produced water, (2) drill cuttings, soil "adjacent to" (3) storage tanks and (4) reserve pits, and (5) pipes and well pad equipment. 3. Define "adjacent to" as between 6 and 12 inches with test samples to be taken within the top 6 inches of soil 4. The rules should also require that the requirements of the Illinois Low Level Radioactivity Waste Management Act be followed.

Sincerely, Aija Nemer-Aanerud Chicago, IL 60615

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Act §1-75(a)7 requires radioactivity testing "once per well site" for (1) flowback water and ground "adjacent to" (2) storage tanks and (3) reserve pits. Act § 1-120 requires IDNR compliance with all "applicable federal, State, and local laws." One applicable State law is the Illinois Low-Level Radioactive Waste Management Act (PA 83-991 / 420ILCS20). Another is the Occupational Health and Safety Administration (OSHA) standards for workplace safety in settings with exposure to radioactivity (29 CFR 1910.1096). Rules §245.850(d)1-E and §245.850(e) are incomplete and deficient, and these inadequacies can "constitute a serious threat"--indeed, deadly threat-- "to the public interest, safety, or welfare" of Illinois citizens." Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Notably absent from these proposed rules is a requirement for the testing of "produced water", the fluid that returns from the well during the later stage of production (after flowback). Under the proposed rules, "produced water" can be stored on site and/or can be "recycled", yet there is no testing requirement. Naturally occurring radioactive material (NORM) is found in "produced water" also. See Technologically enhanced naturally occurring radioactive materials in the oil industry (TENORM), Nukleonika 2009; 54(1):3-9, and sources cited therein, especially for TENORM in produced water in the U.S., available at [http://www.nukleonika.pl/www/back/full/vol54\\_2009/v54n1p003f.pdf](http://www.nukleonika.pl/www/back/full/vol54_2009/v54n1p003f.pdf). See also NORM is also found on scale in oil pipes and on fracking equipment. (See Kentucky Resources Council Proposes Comprehensive Plan For Investigating Radiological Contamination In Martha Oil Field. August 11, 2005. <http://www.kyrc.org/webnewspro/112381723236086.shtml>.) IDNR's definitions of "flowback water" and "produced water" are different. The two are distinguishably different enough that they are treated as separate types of fluid by both the Hydraulic Fracturing Regulatory Act and by the DNR Rules. Discharge of produced water onto the ground or into surface water or water drainage way is prohibited but it is not tested for radioactivity. This despite the fact that this fluid will be in contact with the naturally occurring radioactive elements in the ground for a longer period than the flowback and that it is much more likely to be radioactive. Problems: Failure to test produced water for radioactivity is problematic for a variety of reasons including: The health and safety of workers on the site who will be unaware of the levels of radioactivity they are being exposed to. The health and safety of workers transporting produced water who will also be in the dark regarding the levels of radioactivity they will be exposed to. The risk of storing radioactive material in tanks not created for storing radioactive materials. The risk of "recycling" produced water—radioactivity cannot be removed by recycling. The risk to the public in transporting radioactive materials Argonne National Laboratory recently cautioned about radiological doses: "It is commonly accepted that efforts should be undertaken at all times to keep radiological doses 'as low as reasonably achievable,' which is referred to as the ALARA principle or requirement." Overview of Radiological Dose and Risk Assessment (April 2011). DNR is failing to even adequately test for radioactivity and therefore, will not know the levels of radioactivity. How, then, can

There are two pits on a frack pad, one for "emergency" flowback and another, smaller one for drill cuttings and drilling mud. It is a basic principle in horizontal fracking to steer the drill bit through the horizontal strata with the highest gamma radiation readings (GAPI logs). The reason is that radioactivity correlates highly with total organic content (TOC) in the rock, and TOC correlates highly with oil and gas yields. This means that rock cuttings in the smaller drill mud and cuttings frack pit will often be more radioactive than flowback water. The IDNR knows this; yet it does not call for testing of drill bit pits as allowed under the Powers and duties section of the Act (§1- 15). 3.) The term "adjacent to" requires a "precise, clear standard" [IAPA, §100/5-20]. None is given. Does "adjacent to" mean 6 inches, 16 inches, 6 feet, 16 feet, or 60 feet? The IDNR does not say. 4.) Frack pad pipes and equipment can become incredibly radioactive over time. The very large temperature and pressure drops, as fluids move to the surface from thousands of feet underground, means that aqueous radioactive salts precipitate out as scale on pipes and equipment. The levels of radioactivity in pipe scale can exceed 100,000 picoCuries per gram and constitute a hazard to workers, or others who are exposed to recycled scrap metal from gas and oil operations. Yet, IDNR does not call on its General Assembly deferred "Power and authority" [Act, §1-15(e)] to test pipe, tanks, sludge, and equipment. This issue has been an issue in the oil and gas industry since the 1980s. Consequences: According to studies by the Illinois State Geological Survey, the Illinois New Albany Shale Formation, the source rock for our oil and gas reserves, has above average levels of uranium (29 ppm). Uranium decays into radium and thence radon. Both uranium and radium are water soluble. As noted, the U.S. Geological Survey has found oil field brine or produced water in Southern Illinois to have Radium226 levels that average more than 1,000 picoCuries / liter (USGS 1999). That reading is 67 times above the maximum contamination level of the EPA. Radium226 has a half life of 1,600 years. Uranium228 has a half life of 4.468 billion years. If these water soluble salts leach into our aquifers, nearby communities will require--if possible--very expensive water treatment for the next 1,000 years. We may have to return to rainwater harvesting with the modern equivalent of cisterns. The radioactive levels for produced water from shale gas operations are likely to be 2 to 4 times higher than oilfield brine -- on average, 2,000 to 4,000 picoCuries per liter. In addition, radon levels in methane, propane, and ethane can be dangerously high. When it becomes commercial to extract shale gas from the SE corner of the state, major markets, such as Springfield and Chicago, will only be 0.9 and 1.4 days removed from shale gas wellheads. Even though radon222 has a half life of only 3.8 days, the closeness of major Illinois retail gas markets will mean that large number of people will be breathing in high levels of radon when they cook meals. The average level of indoor exposure to radon in Illinois is already 4.4

## Fair Economy Illinois

---

pCi/L ( American Lung Association 2013). The EPA maximum level--the point at which corrective action should be taken--is 4.0 pCi/L, and the preferred level is =3.0 pCi/L. The turn to shale gas, with its high levels of radon, will also turn a major Illinois public health problem in the wrong direction. Radioactive scale in pipe and equipment presents another problem; high levels of radioactivity have been found in school playground equipment and bleachers in school sports stadiums in Mississippi and Texas. Do we want untested oil and gas field scrap metal sold into Illinois markets? Do we want our children exposed on a daily basis to radioactive metal? The present rules creates no barriers to such an outcome. The problems cited above are why Illinois, with its large number of nuclear power plants, has a Low-Level Radioactive Waste Management Act. It and OSHA are the applicable State and Federal agencies with respect to the issue of radioactive waste and work safety standards in settings with exposure to radioactivity. If we faithfully follow applicable State and federal laws, Illinois can minimize the pernicious problems other states are going to face from the uncontrolled release of radioactive elements into their water and soil and work and non-work settings. We should prevent these problem from the start. Cleanup, after the oil and gas industry is gone, will be dreadfully expensive.. Recommendations: 1. Define the test date as = Day 21, the point at which increases in test results begin to level off. 2. Test for "radioactivity" in (1) flowback/produced water, (2) drill cuttings, soil "adjacent to" (3) storage tanks and (4) reserve pits, and (5) pipes and well pad equipment. 3. Define "adjacent to" as between 6 and 12 inches with test samples to be taken within the top 6 inches of soil 4. The rules should also require that the requirements of the Illinois Low Level Radioactivity Waste Management Act be followed.

Sincerely, Alex Farrenkopf Chicago, IL 60637

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Act §1-75(a)7 requires radioactivity testing "once per well site" for (1) flowback water and ground "adjacent to" (2) storage tanks and (3) reserve pits. Act § 1-120 requires IDNR compliance with all "applicable federal, State, and local laws." One applicable State law is the Illinois Low-Level Radioactive Waste Management Act (PA 83-991 / 420ILCS20). Another is the Occupational Health and Safety Administration (OSHA) standards for workplace safety in settings with exposure to radioactivity (29 CFR 1910.1096). Rules §245.850(d)1-E and §245.850(e) are incomplete and deficient, and these inadequacies can "constitute a serious threat"--indeed, deadly threat-- "to the public interest, safety, or welfare" of Illinois citizens." Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Notably absent from these proposed rules is a requirement for the testing of "produced water", the fluid that returns from the well during the later stage of production (after flowback). Under the proposed rules, "produced water" can be stored on site and/or can be "recycled", yet there is no testing requirement. Naturally occurring radioactive material (NORM) is found in "produced water" also. See Technologically enhanced naturally occurring radioactive materials in the oil industry (TENORM), Nukleonika 2009; 54(1):3-9, and sources cited therein, especially for TENORM in produced water in the U.S., available at [http://www.nukleonika.pl/www/back/full/vol54\\_2009/v54n1p003f.pdf](http://www.nukleonika.pl/www/back/full/vol54_2009/v54n1p003f.pdf). See also NORM is also found on scale in oil pipes and on fracking equipment. (See Kentucky Resources Council Proposes Comprehensive Plan For Investigating Radiological Contamination In Martha Oil Field. August 11, 2005. <http://www.kyrc.org/webnewspro/112381723236086.shtml>.) IDNR's definitions of "flowback water" and "produced water" are different. The two are distinguishably different enough that they are treated as separate types of fluid by both the Hydraulic Fracturing Regulatory Act and by the DNR Rules. Discharge of produced water onto the ground or into surface water or water drainage way is prohibited but it is not tested for radioactivity. This despite the fact that this fluid will be in contact with the naturally occurring radioactive elements in the ground for a longer period than the flowback and that it is much more likely to be radioactive. Problems: Failure to test produced water for radioactivity is problematic for a variety of reasons including: The health and safety of workers on the site who will be unaware of the levels of radioactivity they are being exposed to. The health and safety of workers transporting produced water who will also be in the dark regarding the levels of radioactivity they will be exposed to. The risk of storing radioactive material in tanks not created for storing radioactive materials. The risk of "recycling" produced water—radioactivity cannot be removed by recycling. The risk to the public in transporting radioactive materials Argonne National Laboratory recently cautioned about radiological doses: "It is commonly accepted that efforts should be undertaken at all times to keep radiological doses 'as low as reasonably achievable,' which is referred to as the ALARA principle or requirement." Overview of Radiological Dose and Risk Assessment (April 2011). DNR is failing to even adequately test for radioactivity and therefore, will not know the levels of radioactivity. How, then, can

## Fair Economy Illinois

---

DNR adequately protect workers and the general public? Elaboration: IDNR does not define a Fixed Date ( $\pm X$  days) for testing. Day 1, <Hour 1 test results will be orders of magnitude lower than either Day 2 or Day 10 tests results, and Day 10 tests results will be significantly lower than Day 80 ( $\pm 7$  days) results. Failure to specify a Fixed Test Date ( $\pm X$  days) renders test data so many irrelevant apples and oranges and allows companies to report suppressed, meaningless results by reporting Day 1, < 1 Hour data. The figure below, provided by the USGS, illustrates the nature of the problem. Please note that radium is not tested at Day 1, < 1 Hour. However, radium coprecipitates with barium, which is represented in total dissolved solids (TDS). It will therefore track TDS fairly closely. Conclusion: companies will be testing the very first flowback water to emerge from a fracked well. It will be Day 1, Minute 1 test results. 2.) There are two pits on a frack pad, one for "emergency" flowback and another, smaller one for drill cuttings and drilling mud. It is a basic principle in horizontal fracking to steer the drill bit through the horizontal strata with the highest gamma radiation readings (GAPI logs). The reason is that radioactivity correlates highly with total organic content (TOC) in the rock, and TOC correlates highly with oil and gas yields. This means that rock cuttings in the smaller drill mud and cuttings frack pit will often be more radioactive than flowback water. The IDNR knows this; yet it does not call for testing of drill bit pits as allowed under the Powers and duties section of the Act (§1- 15). 3.) The term "adjacent to" requires a "precise, clear standard" [IAPA, §100/5-20]. None is given. Does "adjacent to" mean 6 inches, 16 inches, 6 feet, 16 feet, or 60 feet? The IDNR does not say. 4.) Frack pad pipes and equipment can become incredibly radioactive over time. The very large temperature and pressure drops, as fluids move to the surface from thousands of feet underground, means that aqueous radioactive salts precipitate out as scale on pipes and equipment. The levels of radioactivity in pipe scale can exceed 100,000 picoCuries per gram and constitute a hazard to workers, or others who are exposed to recycled scrap metal from gas and oil operations. Yet, IDNR does not call on its General Assembly deferred "Power and authority" [Act, §1-15(e)] to test pipe, tanks, sludge, and equipment. This issue has been an issue in the oil and gas industry since the 1980s. Consequences: According to studies by the Illinois State Geological Survey, the Illinois New Albany Shale Formation, the source rock for our oil and gas reserves, has above average levels of uranium (29 ppm). Uranium decays into radium and thence radon. Both uranium and radium are water soluble. As noted, the U.S. Geological Survey has found oil field brine or produced water in Southern Illinois to have Radium226 levels that average more than 1,000 picoCuries / liter (USGS 1999). That reading is 67 times above the maximum contamination level of the EPA. Radium226 has a half life of 1,600 years. Uranium228 has a half life of 4.468 billion years. In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Act §1-75(a)7 requires radioactivity testing "once per well site" for (1) flowback water and ground "adjacent to" (2) storage tanks and (3) reserve pits. Act § 1-120 requires IDNR compliance with all "applicable federal, State, and local laws." One applicable State law is the Illinois Low-Level Radioactive Waste Management Act (PA 83-991 / 420ILCS20). Another is the Occupational Health and Safety Administration (OSHA) standards for workplace safety in settings with exposure to radioactivity (29 CFR 1910.1096). Rules §245.850(d)1-E and §245.850(e) are incomplete and deficient, and these inadequacies can "constitute a serious threat"--indeed, deadly threat-- "to the public interest, safety, or welfare" of Illinois citizens." Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Notably absent from these proposed rules is a requirement for the testing of "produced water", the fluid that returns from the well during the later stage of production (after flowback). Under the proposed rules, "produced water" can be stored on site and/or can be "recycled", yet there is no testing requirement. Naturally occurring radioactive material (NORM) is found in "produced water" also. See Technologically enhanced naturally occurring radioactive materials in the oil industry (TENORM), Nukleonika 2009; 54(1):3-9, and sources cited therein, especially for TENORM in produced water in the U.S., available at [http://www.nukleonika.pl/www/back/full/vol54\\_2009/v54n1p003f.pdf](http://www.nukleonika.pl/www/back/full/vol54_2009/v54n1p003f.pdf). See also NORM is also found on scale in oil pipes and on fracking equipment. (See Kentucky Resources Council Proposes Comprehensive Plan For Investigating Radiological Contamination In Martha Oil Field. August 11, 2005. <http://www.kyrc.org/webnewspro/112381723236086.shtml>.) IDNR's definitions of "flowback water" and "produced water" are different. The two are distinguishably different enough that they are treated as separate types of fluid by both the Hydraulic Fracturing Regulatory Act and by the DNR Rules. Discharge of produced water onto the ground or into surface water or water drainage way is prohibited but it is not tested for radioactivity. This despite the fact that this fluid will be in contact with the naturally occurring radioactive elements in the ground for a longer period than the flowback and that it is much more likely to be radioactive. Problems: Failure to test produced water for radioactivity is problematic for a variety of reasons including: The health and safety of workers on the site who will be unaware of the levels of radioactivity they are being exposed to. The health and safety of workers transporting produced water who will also be in the dark regarding the levels of radioactivity they will be exposed to. The risk of storing radioactive material in tanks not created for storing radioactive materials. The risk of "recycling" produced water—radioactivity cannot be removed by recycling. The risk to the public in transporting radioactive materials Argonne National Laboratory recently cautioned about radiological doses: "It is commonly accepted that efforts should be undertaken at all times to keep radiological doses 'as low as reasonably achievable,' which is referred to as the ALARA principle or requirement." Overview of Radiological Dose and Risk Assessment (April 2011). DNR is failing to even adequately test for radioactivity and therefore, will not know the levels of radioactivity. How, then, can

## Fair Economy Illinois

---

DNR adequately protect workers and the general public? Elaboration: IDNR does not define a Fixed Date ( $\pm X$  days) for testing. Day 1, <Hour 1 test results will be orders of magnitude lower than either Day 2 or Day 10 tests results, and Day 10 tests results will be significantly lower than Day 80 ( $\pm 7$  days) results. Failure to specify a Fixed Test Date ( $\pm X$  days) renders test data so many irrelevant apples and oranges and allows companies to report suppressed, meaningless results by reporting Day 1, < 1 Hour data. The figure below, provided by the USGS, illustrates the nature of the problem. Please note that radium is not tested at Day 1, < 1 Hour. However, radium coprecipitates with barium, which is represented in total dissolved solids (TDS). It will therefore track TDS fairly closely. Conclusion: companies will be testing the very first flowback water to emerge from a fracked well. It will be Day 1, Minute 1 test results. 2.) There are two pits on a frack pad, one for "emergency" flowback and another, smaller one for drill cuttings and drilling mud. It is a basic principle in horizontal fracking to steer the drill bit through the horizontal strata with the highest gamma radiation readings (GAPI logs). The reason is that radioactivity correlates highly with total organic content (TOC) in the rock, and TOC correlates highly with oil and gas yields. This means that rock cuttings in the smaller drill mud and cuttings frack pit will often be more radioactive than flowback water. The IDNR knows this; yet it does not call for testing of drill bit pits as allowed under the Powers and duties section of the Act (§1- 15). 3.) The term "adjacent to" requires a "precise, clear standard" [IAPA, §100/5-20]. None is given. Does "adjacent to" mean 6 inches, 16 inches, 6 feet, 16 feet, or 60 feet? The IDNR does not say. 4.) Frack pad pipes and equipment can become incredibly radioactive over time. The very large temperature and pressure drops, as fluids move to the surface from thousands of feet underground, means that aqueous radioactive salts precipitate out as scale on pipes and equipment. The levels of radioactivity in pipe scale can exceed 100,000 picoCuries per gram and constitute a hazard to workers, or others who are exposed to recycled scrap metal from gas and oil operations. Yet, IDNR does not call on its General Assembly deferred "Power and authority" [Act, §1-15(e)] to test pipe, tanks, sludge, and equipment. This issue has been an issue in the oil and gas industry since the 1980s. Consequences: According to studies by the Illinois State Geological Survey, the Illinois New Albany Shale Formation, the source rock for our oil and gas reserves, has above average levels of uranium (29 ppm). Uranium decays into radium and thence radon. Both uranium and radium are water soluble. As noted, the U.S. Geological Survey has found oil field brine or produced water in Southern Illinois to have Radium226 levels that average more than 1,000 picoCuries / liter (USGS 1999). That reading is 67 times above the maximum contamination level of the EPA. Radium226 has a half life of 1,600 years. Uranium228 has a half life of 4.468 billion years. If these water soluble salts leach into our aquifers, nearby communities will require--if possible--very expensive water treatment for the next 1,000 years. We may have to return to rainwater harvesting with the modern equivalent of cisterns. The radioactive levels for produced water from shale gas operations are likely to be 2 to 4 times higher than oilfield brine -- on average, 2,000 to 4,000 picoCuries per liter. In addition, radon levels in methane, propane, and ethane can be dangerously high. When it becomes commercial to extract shale gas from the SE corner of the state, major markets, such as Springfield and Chicago, will only be 0.9 and 1.4 days removed from shale gas wellheads. Even though radon222 has a half life of only 3.8 days, the closeness of major Illinois retail gas markets will mean that large number of people will be breathing in high levels of radon when they cook meals. The average level of indoor exposure to radon in Illinois is already 4.4

## Fair Economy Illinois

---

pCi/L ( American Lung Association 2013). The EPA maximum level--the point at which corrective action should be taken--is 4.0 pCi/L, and the preferred level is =3.0 pCi/L. The turn to shale gas, with its high levels of radon, will also turn a major Illinois public health problem in the wrong direction. Radioactive scale in pipe and equipment presents another problem; high levels of radioactivity have been found in school playground equipment and bleachers in school sports stadiums in Mississippi and Texas. Do we want untested oil and gas field scrap metal sold into Illinois markets? Do we want our children exposed on a daily basis to radioactive metal? The present rules creates no barriers to such an outcome. The problems cited above are why Illinois, with its large number of nuclear power plants, has a Low-Level Radioactive Waste Management Act. It and OSHA are the applicable State and Federal agencies with respect to the issue of radioactive waste and work safety standards in settings with exposure to radioactivity. If we faithfully follow applicable State and federal laws, Illinois can minimize the pernicious problems other states are going to face from the uncontrolled release of radioactive elements into their water and soil and work and non-work settings. We should prevent these problem from the start. Cleanup, after the oil and gas industry is gone, will be dreadfully expensive.. Recommendations: 1. Define the test date as = Day 21, the point at which increases in test results begin to level off. 2. Test for "radioactivity" in (1) flowback/produced water, (2) drill cuttings, soil "adjacent to" (3) storage tanks and (4) reserve pits, and (5) pipes and well pad equipment. 3. Define "adjacent to" as between 6 and 12 inches with test samples to be taken within the top 6 inches of soil 4. The rules should also require that the requirements of the Illinois Low Level Radioactivity Waste Management Act be followed.

Sincerely, Alyssa Carabez Carabez Brookfield, IL 60573

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Act §1-75(a)7 requires radioactivity testing "once per well site" for (1) flowback water and ground "adjacent to" (2) storage tanks and (3) reserve pits. Act § 1-120 requires IDNR compliance with all "applicable federal, State, and local laws." One applicable State law is the Illinois Low-Level Radioactive Waste Management Act (PA 83-991 / 420ILCS20). Another is the Occupational Health and Safety Administration (OSHA) standards for workplace safety in settings with exposure to radioactivity (29 CFR 1910.1096). Rules §245.850(d)1-E and §245.850(e) are incomplete and deficient, and these inadequacies can "constitute a serious threat"--indeed, deadly threat-- "to the public interest, safety, or welfare" of Illinois citizens." Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Notably absent from these proposed rules is a requirement for the testing of "produced water", the fluid that returns from the well during the later stage of production (after flowback). Under the proposed rules, "produced water" can be stored on site and/or can be "recycled", yet there is no testing requirement. Naturally occurring radioactive material (NORM) is found in "produced water" also. See Technologically enhanced naturally occurring radioactive materials in the oil industry (TENORM), Nukleonika 2009; 54(1):3-9, and sources cited therein, especially for TENORM in produced water in the U.S., available at [http://www.nukleonika.pl/www/back/full/vol54\\_2009/v54n1p003f.pdf](http://www.nukleonika.pl/www/back/full/vol54_2009/v54n1p003f.pdf). See also NORM is also found on scale in oil pipes and on fracking equipment. (See Kentucky Resources Council Proposes Comprehensive Plan For Investigating Radiological Contamination In Martha Oil Field. August 11, 2005. <http://www.kyrc.org/webnewspro/112381723236086.shtml>.) IDNR's definitions of "flowback water" and "produced water" are different. The two are distinguishably different enough that they are treated as separate types of fluid by both the Hydraulic Fracturing Regulatory Act and by the DNR Rules. Discharge of produced water onto the ground or into surface water or water drainage way is prohibited but it is not tested for radioactivity. This despite the fact that this fluid will be in contact with the naturally occurring radioactive elements in the ground for a longer period than the flowback and that it is much more likely to be radioactive. Problems: Failure to test produced water for radioactivity is problematic for a variety of reasons including: The health and safety of workers on the site who will be unaware of the levels of radioactivity they are being exposed to. The health and safety of workers transporting produced water who will also be in the dark regarding the levels of radioactivity they will be exposed to. The risk of storing radioactive material in tanks not created for storing radioactive materials. The risk of "recycling" produced water—radioactivity cannot be removed by recycling. The risk to the public in transporting radioactive materials Argonne National Laboratory recently cautioned about radiological doses: "It is commonly accepted that efforts should be undertaken at all times to keep radiological doses 'as low as reasonably achievable,' which is referred to as the ALARA principle or requirement." Overview of Radiological Dose and Risk Assessment (April 2011). DNR is failing to even adequately test for radioactivity and therefore, will not know the levels of radioactivity. How, then, can

DNR adequately protect workers and the general public? Elaboration: IDNR does not define a Fixed Date ( $\pm X$  days) for testing. Day 1, <Hour 1 test results will be orders of magnitude lower than either Day 2 or Day 10 tests results, and Day 10 tests results will be significantly lower than Day 80 ( $\pm 7$  days) results. Failure to specify a Fixed Test Date ( $\pm X$  days) renders test data so many irrelevant apples and oranges and allows companies to report suppressed, meaningless results by reporting Day 1, < 1 Hour data. The figure below, provided by the USGS, illustrates the nature of the problem. Please note that radium is not tested at Day 1, < 1 Hour. However, radium coprecipitates with barium, which is represented in total dissolved solids (TDS). It will therefore track TDS fairly closely. Conclusion: companies will be testing the very first flowback water to emerge from a fracked well. It will be Day 1, Minute 1 test results. 2.) There are two pits on a frack pad, one for "emergency" flowback and another, smaller one for drill cuttings and drilling mud. It is a basic principle in horizontal fracking to steer the drill bit through the horizontal strata with the highest gamma radiation readings (GAPI logs). The reason is that radioactivity correlates highly with total organic content (TOC) in the rock, and TOC correlates highly with oil and gas yields. This means that rock cuttings in the smaller drill mud and cuttings frack pit will often be more radioactive than flowback water. The IDNR knows this; yet it does not call for testing of drill bit pits as allowed under the Powers and duties section of the Act (§1- 15). 3.) The term "adjacent to" requires a "precise, clear standard" [IAPA, §100/5-20]. None is given. Does "adjacent to" mean 6 inches, 16 inches, 6 feet, 16 feet, or 60 feet? The IDNR does not say. 4.) Frack pad pipes and equipment can become incredibly radioactive over time. The very large temperature and pressure drops, as fluids move to the surface from thousands of feet underground, means that aqueous radioactive salts precipitate out as scale on pipes and equipment. The levels of radioactivity in pipe scale can exceed 100,000 picoCuries per gram and constitute a hazard to workers, or others who are exposed to recycled scrap metal from gas and oil operations. Yet, IDNR does not call on its General Assembly deferred "Power and authority" [Act, §1-15(e)] to test pipe, tanks, sludge, and equipment. This issue has been an issue in the oil and gas industry since the 1980s. Consequences: According to studies by the Illinois State Geological Survey, the Illinois New Albany Shale Formation, the source rock for our oil and gas reserves, has above average levels of uranium (29 ppm). Uranium decays into radium and thence radon. Both uranium and radium are water soluble. As noted, the U.S. Geological Survey has found oil field brine or produced water in Southern Illinois to have Radium226 levels that average more than 1,000 picoCuries / liter (USGS 1999). That reading is 67 times above the maximum contamination level of the EPA. Radium226 has a half life of 1,600 years. Uranium228 has a half life of 4.468 billion years. If these water soluble salts leach into our aquifers, nearby communities will require--if possible--very expensive water treatment for the next 1,000 years. We may have to return to rainwater harvesting with the modern equivalent of cisterns. The radioactive levels for produced water from shale gas operations are likely to be 2 to 4 times higher than oilfield brine -- on average, 2,000 to 4,000 picoCuries per liter. In addition, radon levels in methane, propane, and ethane can be dangerously high. When it becomes commercial to extract shale gas from the SE corner of the state, major markets, such as Springfield and Chicago, will only be 0.9 and 1.4 days removed from shale gas wellheads. Even though radon222 has a half life of only 3.8 days, the closeness of major Illinois retail gas markets will mean that large number of people will be breathing in high levels of radon when they cook meals. The average level of indoor exposure to radon in Illinois is already 4.4

## Fair Economy Illinois

---

pCi/L ( American Lung Association 2013). The EPA maximum level--the point at which corrective action should be taken--is 4.0 pCi/L, and the preferred level is =3.0 pCi/L. The turn to shale gas, with its high levels of radon, will also turn a major Illinois public health problem in the wrong direction. Radioactive scale in pipe and equipment presents another problem; high levels of radioactivity have been found in school playground equipment and bleachers in school sports stadiums in Mississippi and Texas. Do we want untested oil and gas field scrap metal sold into Illinois markets? Do we want our children exposed on a daily basis to radioactive metal? The present rules creates no barriers to such an outcome. The problems cited above are why Illinois, with its large number of nuclear power plants, has a Low-Level Radioactive Waste Management Act. It and OSHA are the applicable State and Federal agencies with respect to the issue of radioactive waste and work safety standards in settings with exposure to radioactivity. If we faithfully follow applicable State and federal laws, Illinois can minimize the pernicious problems other states are going to face from the uncontrolled release of radioactive elements into their water and soil and work and non-work settings. We should prevent these problem from the start. Cleanup, after the oil and gas industry is gone, will be dreadfully expensive.. Recommendations: 1. Define the test date as = Day 21, the point at which increases in test results begin to level off. 2. Test for "radioactivity" in (1) flowback/produced water, (2) drill cuttings, soil "adjacent to" (3) storage tanks and (4) reserve pits, and (5) pipes and well pad equipment. 3. Define "adjacent to" as between 6 and 12 inches with test samples to be taken within the top 6 inches of soil 4. The rules should also require that the requirements of the Illinois Low Level Radioactivity Waste Management Act be followed.

Sincerely, andrew hwang Chicago, IL 60615

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Act §1-75(a)7 requires radioactivity testing "once per well site" for (1) flowback water and ground "adjacent to" (2) storage tanks and (3) reserve pits. Act § 1-120 requires IDNR compliance with all "applicable federal, State, and local laws." One applicable State law is the Illinois Low-Level Radioactive Waste Management Act (PA 83-991 / 420ILCS20). Another is the Occupational Health and Safety Administration (OSHA) standards for workplace safety in settings with exposure to radioactivity (29 CFR 1910.1096). Rules §245.850(d)1-E and §245.850(e) are incomplete and deficient, and these inadequacies can "constitute a serious threat"--indeed, deadly threat-- "to the public interest, safety, or welfare" of Illinois citizens." Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Notably absent from these proposed rules is a requirement for the testing of "produced water", the fluid that returns from the well during the later stage of production (after flowback). Under the proposed rules, "produced water" can be stored on site and/or can be "recycled", yet there is no testing requirement. Naturally occurring radioactive material (NORM) is found in "produced water" also. See Technologically enhanced naturally occurring radioactive materials in the oil industry (TENORM), Nukleonika 2009; 54(1):3-9, and sources cited therein, especially for TENORM in produced water in the U.S., available at [http://www.nukleonika.pl/www/back/full/vol54\\_2009/v54n1p003f.pdf](http://www.nukleonika.pl/www/back/full/vol54_2009/v54n1p003f.pdf). See also NORM is also found on scale in oil pipes and on fracking equipment. (See Kentucky Resources Council Proposes Comprehensive Plan For Investigating Radiological Contamination In Martha Oil Field. August 11, 2005. <http://www.kyrc.org/webnewspro/112381723236086.shtml>.) IDNR's definitions of "flowback water" and "produced water" are different. The two are distinguishably different enough that they are treated as separate types of fluid by both the Hydraulic Fracturing Regulatory Act and by the DNR Rules. Discharge of produced water onto the ground or into surface water or water drainage way is prohibited but it is not tested for radioactivity. This despite the fact that this fluid will be in contact with the naturally occurring radioactive elements in the ground for a longer period than the flowback and that it is much more likely to be radioactive. Problems: Failure to test produced water for radioactivity is problematic for a variety of reasons including: The health and safety of workers on the site who will be unaware of the levels of radioactivity they are being exposed to. The health and safety of workers transporting produced water who will also be in the dark regarding the levels of radioactivity they will be exposed to. The risk of storing radioactive material in tanks not created for storing radioactive materials. The risk of "recycling" produced water—radioactivity cannot be removed by recycling. The risk to the public in transporting radioactive materials Argonne National Laboratory recently cautioned about radiological doses: "It is commonly accepted that efforts should be undertaken at all times to keep radiological doses 'as low as reasonably achievable,' which is referred to as the ALARA principle or requirement." Overview of Radiological Dose and Risk Assessment (April 2011). DNR is failing to even adequately test for radioactivity and therefore, will not know the levels of radioactivity. How, then, can

## Fair Economy Illinois

---

DNR adequately protect workers and the general public? Elaboration: IDNR does not define a Fixed Date ( $\pm X$  days) for testing. Day 1, <Hour 1 test results will be orders of magnitude lower than either Day 2 or Day 10 tests results, and Day 10 tests results will be significantly lower than Day 80 ( $\pm 7$  days) results. Failure to specify a Fixed Test Date ( $\pm X$  days) renders test data so many irrelevant apples and oranges and allows companies to report suppressed, meaningless results by reporting Day 1, < 1 Hour data. The figure below, provided by the USGS, illustrates the nature of the problem. Please note that radium is not tested at Day 1, < 1 Hour. However, radium coprecipitates with barium, which is represented in total dissolved solids (TDS). It will therefore track TDS fairly closely. Conclusion: companies will be testing the very first flowback water to emerge from a fracked well. It will be Day 1, Minute 1 test results. 2.) There are two pits on a frack pad, one for "emergency" flowback and another, smaller one for drill cuttings and drilling mud. It is a basic principle in horizontal fracking to steer the drill bit through the horizontal strata with the highest gamma radiation readings (GAPI logs). The reason is that radioactivity correlates highly with total organic content (TOC) in the rock, and TOC correlates highly with oil and gas yields. This means that rock cuttings in the smaller drill mud and cuttings frack pit will often be more radioactive than flowback water. The IDNR knows this; yet it does not call for testing of drill bit pits as allowed under the Powers and duties section of the Act (§1- 15). 3.) The term "adjacent to" requires a "precise, clear standard" [IAPA, §100/5-20]. None is given. Does "adjacent to" mean 6 inches, 16 inches, 6 feet, 16 feet, or 60 feet? The IDNR does not say. 4.) Frack pad pipes and equipment can become incredibly radioactive over time. The very large temperature and pressure drops, as fluids move to the surface from thousands of feet underground, means that aqueous radioactive salts precipitate out as scale on pipes and equipment. The levels of radioactivity in pipe scale can exceed 100,000 picoCuries per gram and constitute a hazard to workers, or others who are exposed to recycled scrap metal from gas and oil operations. Yet, IDNR does not call on its General Assembly deferred "Power and authority" [Act, §1-15(e)] to test pipe, tanks, sludge, and equipment. This issue has been an issue in the oil and gas industry since the 1980s. Consequences: According to studies by the Illinois State Geological Survey, the Illinois New Albany Shale Formation, the source rock for our oil and gas reserves, has above average levels of uranium (29 ppm). Uranium decays into radium and thence radon. Both uranium and radium are water soluble. As noted, the U.S. Geological Survey has found oil field brine or produced water in Southern Illinois to have Radium226 levels that average more than 1,000 picoCuries / liter (USGS 1999). That reading is 67 times above the maximum contamination level of the EPA. Radium226 has a half life of 1,600 years. Uranium228 has a half life of 4.468 billion years. If these water soluble salts leach into our aquifers, nearby communities will require--if possible--very expensive water treatment for the next 1,000 years. We may have to return to rainwater harvesting with the modern equivalent of cisterns. The radioactive levels for produced water from shale gas operations are likely to be 2 to 4 times higher than oilfield brine -- on average, 2,000 to 4,000 picoCuries per liter. In addition, radon levels in methane, propane, and ethane can be dangerously high. When it becomes commercial to extract shale gas from the SE corner of the state, major markets, such as Springfield and Chicago, will only be 0.9 and 1.4 days removed from shale gas wellheads. Even though radon222 has a half life of only 3.8 days, the closeness of major Illinois retail gas markets will mean that large number of people will be breathing in high levels of radon when they cook meals. The average level of indoor exposure to radon in Illinois is already 4.4

## Fair Economy Illinois

---

pCi/L ( American Lung Association 2013). The EPA maximum level--the point at which corrective action should be taken--is 4.0 pCi/L, and the preferred level is =3.0 pCi/L. The turn to shale gas, with its high levels of radon, will also turn a major Illinois public health problem in the wrong direction. Radioactive scale in pipe and equipment presents another problem; high levels of radioactivity have been found in school playground equipment and bleachers in school sports stadiums in Mississippi and Texas. Do we want untested oil and gas field scrap metal sold into Illinois markets? Do we want our children exposed on a daily basis to radioactive metal? The present rules creates no barriers to such an outcome. The problems cited above are why Illinois, with its large number of nuclear power plants, has a Low-Level Radioactive Waste Management Act. It and OSHA are the applicable State and Federal agencies with respect to the issue of radioactive waste and work safety standards in settings with exposure to radioactivity. If we faithfully follow applicable State and federal laws, Illinois can minimize the pernicious problems other states are going to face from the uncontrolled release of radioactive elements into their water and soil and work and non-work settings. We should prevent these problem from the start. Cleanup, after the oil and gas industry is gone, will be dreadfully expensive.. Recommendations: 1. Define the test date as = Day 21, the point at which increases in test results begin to level off. 2. Test for "radioactivity" in (1) flowback/produced water, (2) drill cuttings, soil "adjacent to" (3) storage tanks and (4) reserve pits, and (5) pipes and well pad equipment. 3. Define "adjacent to" as between 6 and 12 inches with test samples to be taken within the top 6 inches of soil 4. The rules should also require that the requirements of the Illinois Low Level Radioactivity Waste Management Act be followed.

Sincerely, Andrew Sigman Chicago, IL 60651

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Act §1-75(a)7 requires radioactivity testing "once per well site" for (1) flowback water and ground "adjacent to" (2) storage tanks and (3) reserve pits. Act § 1-120 requires IDNR compliance with all "applicable federal, State, and local laws." One applicable State law is the Illinois Low-Level Radioactive Waste Management Act (PA 83-991 / 420ILCS20). Another is the Occupational Health and Safety Administration (OSHA) standards for workplace safety in settings with exposure to radioactivity (29 CFR 1910.1096). Rules §245.850(d)1-E and §245.850(e) are incomplete and deficient, and these inadequacies can "constitute a serious threat"--indeed, deadly threat-- "to the public interest, safety, or welfare" of Illinois citizens." Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Notably absent from these proposed rules is a requirement for the testing of "produced water", the fluid that returns from the well during the later stage of production (after flowback). Under the proposed rules, "produced water" can be stored on site and/or can be "recycled", yet there is no testing requirement. Naturally occurring radioactive material (NORM) is found in "produced water" also. See Technologically enhanced naturally occurring radioactive materials in the oil industry (TENORM), Nukleonika 2009; 54(1):3-9, and sources cited therein, especially for TENORM in produced water in the U.S., available at [http://www.nukleonika.pl/www/back/full/vol54\\_2009/v54n1p003f.pdf](http://www.nukleonika.pl/www/back/full/vol54_2009/v54n1p003f.pdf). See also NORM is also found on scale in oil pipes and on fracking equipment. (See Kentucky Resources Council Proposes Comprehensive Plan For Investigating Radiological Contamination In Martha Oil Field. August 11, 2005. <http://www.kyrc.org/webnewspro/112381723236086.shtml>.) IDNR's definitions of "flowback water" and "produced water" are different. The two are distinguishably different enough that they are treated as separate types of fluid by both the Hydraulic Fracturing Regulatory Act and by the DNR Rules. Discharge of produced water onto the ground or into surface water or water drainage way is prohibited but it is not tested for radioactivity. This despite the fact that this fluid will be in contact with the naturally occurring radioactive elements in the ground for a longer period than the flowback and that it is much more likely to be radioactive. Problems: Failure to test produced water for radioactivity is problematic for a variety of reasons including: The health and safety of workers on the site who will be unaware of the levels of radioactivity they are being exposed to. The health and safety of workers transporting produced water who will also be in the dark regarding the levels of radioactivity they will be exposed to. The risk of storing radioactive material in tanks not created for storing radioactive materials. The risk of "recycling" produced water—radioactivity cannot be removed by recycling. The risk to the public in transporting radioactive materials Argonne National Laboratory recently cautioned about radiological doses: "It is commonly accepted that efforts should be undertaken at all times to keep radiological doses 'as low as reasonably achievable,' which is referred to as the ALARA principle or requirement." Overview of Radiological Dose and Risk Assessment (April 2011). DNR is failing to even adequately test for radioactivity and therefore, will not know the levels of radioactivity. How, then, can

## Fair Economy Illinois

---

DNR adequately protect workers and the general public? Elaboration: IDNR does not define a Fixed Date ( $\pm X$  days) for testing. Day 1, <Hour 1 test results will be orders of magnitude lower than either Day 2 or Day 10 tests results, and Day 10 tests results will be significantly lower than Day 80 ( $\pm 7$  days) results. Failure to specify a Fixed Test Date ( $\pm X$  days) renders test data so many irrelevant apples and oranges and allows companies to report suppressed, meaningless results by reporting Day 1, < 1 Hour data. The figure below, provided by the USGS, illustrates the nature of the problem. Please note that radium is not tested at Day 1, < 1 Hour. However, radium coprecipitates with barium, which is represented in total dissolved solids (TDS). It will therefore track TDS fairly closely. Conclusion: companies will be testing the very first flowback water to emerge from a fracked well. It will be Day 1, Minute 1 test results. 2.) There are two pits on a frack pad, one for "emergency" flowback and another, smaller one for drill cuttings and drilling mud. It is a basic principle in horizontal fracking to steer the drill bit through the horizontal strata with the highest gamma radiation readings (GAPI logs). The reason is that radioactivity correlates highly with total organic content (TOC) in the rock, and TOC correlates highly with oil and gas yields. This means that rock cuttings in the smaller drill mud and cuttings frack pit will often be more radioactive than flowback water. The IDNR knows this; yet it does not call for testing of drill bit pits as allowed under the Powers and duties section of the Act (§1- 15). 3.) The term "adjacent to" requires a "precise, clear standard" [IAPA, §100/5-20]. None is given. Does "adjacent to" mean 6 inches, 16 inches, 6 feet, 16 feet, or 60 feet? The IDNR does not say. 4.) Frack pad pipes and equipment can become incredibly radioactive over time. The very large temperature and pressure drops, as fluids move to the surface from thousands of feet underground, means that aqueous radioactive salts precipitate out as scale on pipes and equipment. The levels of radioactivity in pipe scale can exceed 100,000 picoCuries per gram and constitute a hazard to workers, or others who are exposed to recycled scrap metal from gas and oil operations. Yet, IDNR does not call on its General Assembly deferred "Power and authority" [Act, §1-15(e)] to test pipe, tanks, sludge, and equipment. This issue has been an issue in the oil and gas industry since the 1980s. If we faithfully follow applicable State and federal laws, Illinois can minimize the pernicious problems other states are going to face from the uncontrolled release of radioactive elements into their water and soil and work and non-work settings. We should prevent these problem from the start. Cleanup, after the oil and gas industry is gone, will be dreadfully expensive.. Recommendations: 1. Define the test date as = Day 21, the point at which increases in test results begin to level off. 2. Test for "radioactivity" in (1) flowback/produced water, (2) drill cuttings, soil "adjacent to" (3) storage tanks and (4) reserve pits, and (5) pipes and well pad equipment. 3. Define "adjacent to" as between 6 and 12 inches with test samples to be taken within the top 6 inches of soil 4. The rules should also require that the requirements of the Illinois Low Level Radioactivity Waste Management Act be followed.

Sincerely, Anica Washington Chicago, IL 60619

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Act §1-75(a)7 requires radioactivity testing "once per well site" for (1) flowback water and ground "adjacent to" (2) storage tanks and (3) reserve pits. Act § 1-120 requires IDNR compliance with all "applicable federal, State, and local laws." One applicable State law is the Illinois Low-Level Radioactive Waste Management Act (PA 83-991 / 420ILCS20). Another is the Occupational Health and Safety Administration (OSHA) standards for workplace safety in settings with exposure to radioactivity (29 CFR 1910.1096). Rules §245.850(d)1-E and §245.850(e) are incomplete and deficient, and these inadequacies can "constitute a serious threat"--indeed, deadly threat-- "to the public interest, safety, or welfare" of Illinois citizens." Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Notably absent from these proposed rules is a requirement for the testing of "produced water", the fluid that returns from the well during the later stage of production (after flowback). Under the proposed rules, "produced water" can be stored on site and/or can be "recycled", yet there is no testing requirement. Naturally occurring radioactive material (NORM) is found in "produced water" also. See Technologically enhanced naturally occurring radioactive materials in the oil industry (TENORM), Nukleonika 2009; 54(1):3-9, and sources cited therein, especially for TENORM in produced water in the U.S., available at [http://www.nukleonika.pl/www/back/full/vol54\\_2009/v54n1p003f.pdf](http://www.nukleonika.pl/www/back/full/vol54_2009/v54n1p003f.pdf). See also NORM is also found on scale in oil pipes and on fracking equipment. (See Kentucky Resources Council Proposes Comprehensive Plan For Investigating Radiological Contamination In Martha Oil Field. August 11, 2005. <http://www.kyrc.org/webnewspro/112381723236086.shtml>.) IDNR's definitions of "flowback water" and "produced water" are different. The two are distinguishably different enough that they are treated as separate types of fluid by both the Hydraulic Fracturing Regulatory Act and by the DNR Rules. Discharge of produced water onto the ground or into surface water or water drainage way is prohibited but it is not tested for radioactivity. This despite the fact that this fluid will be in contact with the naturally occurring radioactive elements in the ground for a longer period than the flowback and that it is much more likely to be radioactive. Problems: Failure to test produced water for radioactivity is problematic for a variety of reasons including: The health and safety of workers on the site who will be unaware of the levels of radioactivity they are being exposed to. The health and safety of workers transporting produced water who will also be in the dark regarding the levels of radioactivity they will be exposed to. The risk of storing radioactive material in tanks not created for storing radioactive materials. The risk of "recycling" produced water—radioactivity cannot be removed by recycling. The risk to the public in transporting radioactive materials Argonne National Laboratory recently cautioned about radiological doses: "It is commonly accepted that efforts should be undertaken at all times to keep radiological doses 'as low as reasonably achievable,' which is referred to as the ALARA principle or requirement." Overview of Radiological Dose and Risk Assessment (April 2011). DNR is failing to even adequately test for radioactivity and therefore, will not know the levels of radioactivity. How, then, can

## Fair Economy Illinois

---

DNR adequately protect workers and the general public? Elaboration: IDNR does not define a Fixed Date ( $\pm X$  days) for testing. Day 1, <Hour 1 test results will be orders of magnitude lower than either Day 2 or Day 10 tests results, and Day 10 tests results will be significantly lower than Day 80 ( $\pm 7$  days) results. Failure to specify a Fixed Test Date ( $\pm X$  days) renders test data so many irrelevant apples and oranges and allows companies to report suppressed, meaningless results by reporting Day 1, < 1 Hour data. The figure below, provided by the USGS, illustrates the nature of the problem. Please note that radium is not tested at Day 1, < 1 Hour. However, radium coprecipitates with barium, which is represented in total dissolved solids (TDS). It will therefore track TDS fairly closely. Conclusion: companies will be testing the very first flowback water to emerge from a fracked well. It will be Day 1, Minute 1 test results. 2.) There are two pits on a frack pad, one for "emergency" flowback and another, smaller one for drill cuttings and drilling mud. It is a basic principle in horizontal fracking to steer the drill bit through the horizontal strata with the highest gamma radiation readings (GAPI logs). The reason is that radioactivity correlates highly with total organic content (TOC) in the rock, and TOC correlates highly with oil and gas yields. This means that rock cuttings in the smaller drill mud and cuttings frack pit will often be more radioactive than flowback water. The IDNR knows this; yet it does not call for testing of drill bit pits as allowed under the Powers and duties section of the Act (§1- 15). 3.) The term "adjacent to" requires a "precise, clear standard" [IAPA, §100/5-20]. None is given. Does "adjacent to" mean 6 inches, 16 inches, 6 feet, 16 feet, or 60 feet? The IDNR does not say. 4.) Frack pad pipes and equipment can become incredibly radioactive over time. The very large temperature and pressure drops, as fluids move to the surface from thousands of feet underground, means that aqueous radioactive salts precipitate out as scale on pipes and equipment. The levels of radioactivity in pipe scale can exceed 100,000 picoCuries per gram and constitute a hazard to workers, or others who are exposed to recycled scrap metal from gas and oil operations. Yet, IDNR does not call on its General Assembly deferred "Power and authority" [Act, §1-15(e)] to test pipe, tanks, sludge, and equipment. This issue has been an issue in the oil and gas industry since the 1980s. Consequences: According to studies by the Illinois State Geological Survey, the Illinois New Albany Shale Formation, the source rock for our oil and gas reserves, has above average levels of uranium (29 ppm). Uranium decays into radium and thence radon. Both uranium and radium are water soluble. As noted, the U.S. Geological Survey has found oil field brine or produced water in Southern Illinois to have Radium226 levels that average more than 1,000 picoCuries / liter (USGS 1999). That reading is 67 times above the maximum contamination level of the EPA. Radium226 has a half life of 1,600 years. Uranium228 has a half life of 4.468 billion years. If these water soluble salts leach into our aquifers, nearby communities will require--if possible--very expensive water treatment for the next 1,000 years. We may have to return to rainwater harvesting with the modern equivalent of cisterns. The radioactive levels for produced water from shale gas operations are likely to be 2 to 4 times higher than oilfield brine -- on average, 2,000 to 4,000 picoCuries per liter. In addition, radon levels in methane, propane, and ethane can be dangerously high. When it becomes commercial to extract shale gas from the SE corner of the state, major markets, such as Springfield and Chicago, will only be 0.9 and 1.4 days removed from shale gas wellheads. Even though radon222 has a half life of only 3.8 days, the closeness of major Illinois retail gas markets will mean that large number of people will be breathing in high levels of radon when they cook meals. The average level of indoor exposure to radon in Illinois is already 4.4

## Fair Economy Illinois

---

pCi/L ( American Lung Association 2013). The EPA maximum level--the point at which corrective action should be taken--is 4.0 pCi/L, and the preferred level is =3.0 pCi/L. The turn to shale gas, with its high levels of radon, will also turn a major Illinois public health problem in the wrong direction. Radioactive scale in pipe and equipment presents another problem; high levels of radioactivity have been found in school playground equipment and bleachers in school sports stadiums in Mississippi and Texas. Do we want untested oil and gas field scrap metal sold into Illinois markets? Do we want our children exposed on a daily basis to radioactive metal? The present rules creates no barriers to such an outcome. The problems cited above are why Illinois, with its large number of nuclear power plants, has a Low-Level Radioactive Waste Management Act. It and OSHA are the applicable State and Federal agencies with respect to the issue of radioactive waste and work safety standards in settings with exposure to radioactivity. If we faithfully follow applicable State and federal laws, Illinois can minimize the pernicious problems other states are going to face from the uncontrolled release of radioactive elements into their water and soil and work and non-work settings. We should prevent these problem from the start. Cleanup, after the oil and gas industry is gone, will be dreadfully expensive.. Recommendations: 1. Define the test date as = Day 21, the point at which increases in test results begin to level off. 2. Test for "radioactivity" in (1) flowback/produced water, (2) drill cuttings, soil "adjacent to" (3) storage tanks and (4) reserve pits, and (5) pipes and well pad equipment. 3. Define "adjacent to" as between 6 and 12 inches with test samples to be taken within the top 6 inches of soil 4. The rules should also require that the requirements of the Illinois Low Level Radioactivity Waste Management Act be followed.

Sincerely, Anna Betts Chicago, IL 60607

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Act §1-75(a)7 requires radioactivity testing "once per well site" for (1) flowback water and ground "adjacent to" (2) storage tanks and (3) reserve pits. Act § 1-120 requires IDNR compliance with all "applicable federal, State, and local laws." One applicable State law is the Illinois Low-Level Radioactive Waste Management Act (PA 83-991 / 420ILCS20). Another is the Occupational Health and Safety Administration (OSHA) standards for workplace safety in settings with exposure to radioactivity (29 CFR 1910.1096). Rules §245.850(d)1-E and §245.850(e) are incomplete and deficient, and these inadequacies can "constitute a serious threat"--indeed, deadly threat-- "to the public interest, safety, or welfare" of Illinois citizens." Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Notably absent from these proposed rules is a requirement for the testing of "produced water", the fluid that returns from the well during the later stage of production (after flowback). Under the proposed rules, "produced water" can be stored on site and/or can be "recycled", yet there is no testing requirement. Naturally occurring radioactive material (NORM) is found in "produced water" also. See Technologically enhanced naturally occurring radioactive materials in the oil industry (TENORM), Nukleonika 2009; 54(1):3-9, and sources cited therein, especially for TENORM in produced water in the U.S., available at [http://www.nukleonika.pl/www/back/full/vol54\\_2009/v54n1p003f.pdf](http://www.nukleonika.pl/www/back/full/vol54_2009/v54n1p003f.pdf). See also NORM is also found on scale in oil pipes and on fracking equipment. (See Kentucky Resources Council Proposes Comprehensive Plan For Investigating Radiological Contamination In Martha Oil Field. August 11, 2005. <http://www.kyrc.org/webnewspro/112381723236086.shtml>.) IDNR's definitions of "flowback water" and "produced water" are different. The two are distinguishably different enough that they are treated as separate types of fluid by both the Hydraulic Fracturing Regulatory Act and by the DNR Rules. Discharge of produced water onto the ground or into surface water or water drainage way is prohibited but it is not tested for radioactivity. This despite the fact that this fluid will be in contact with the naturally occurring radioactive elements in the ground for a longer period than the flowback and that it is much more likely to be radioactive. Problems: Failure to test produced water for radioactivity is problematic for a variety of reasons including: The health and safety of workers on the site who will be unaware of the levels of radioactivity they are being exposed to. The health and safety of workers transporting produced water who will also be in the dark regarding the levels of radioactivity they will be exposed to. The risk of storing radioactive material in tanks not created for storing radioactive materials. The risk of "recycling" produced water—radioactivity cannot be removed by recycling. The risk to the public in transporting radioactive materials Argonne National Laboratory recently cautioned about radiological doses: "It is commonly accepted that efforts should be undertaken at all times to keep radiological doses 'as low as reasonably achievable,' which is referred to as the ALARA principle or requirement." Overview of Radiological Dose and Risk Assessment (April 2011). DNR is failing to even adequately test for radioactivity and therefore, will not know the levels of radioactivity. How, then, can

## Fair Economy Illinois

---

DNR adequately protect workers and the general public? Elaboration: IDNR does not define a Fixed Date ( $\pm X$  days) for testing. Day 1, <Hour 1 test results will be orders of magnitude lower than either Day 2 or Day 10 tests results, and Day 10 tests results will be significantly lower than Day 80 ( $\pm 7$  days) results. Failure to specify a Fixed Test Date ( $\pm X$  days) renders test data so many irrelevant apples and oranges and allows companies to report suppressed, meaningless results by reporting Day 1, < 1 Hour data. The figure below, provided by the USGS, illustrates the nature of the problem. Please note that radium is not tested at Day 1, < 1 Hour. However, radium coprecipitates with barium, which is represented in total dissolved solids (TDS). It will therefore track TDS fairly closely. Conclusion: companies will be testing the very first flowback water to emerge from a fracked well. It will be Day 1, Minute 1 test results. 2.) There are two pits on a frack pad, one for "emergency" flowback and another, smaller one for drill cuttings and drilling mud. It is a basic principle in horizontal fracking to steer the drill bit through the horizontal strata with the highest gamma radiation readings (GAPI logs). The reason is that radioactivity correlates highly with total organic content (TOC) in the rock, and TOC correlates highly with oil and gas yields. This means that rock cuttings in the smaller drill mud and cuttings frack pit will often be more radioactive than flowback water. The IDNR knows this; yet it does not call for testing of drill bit pits as allowed under the Powers and duties section of the Act (§1- 15). 3.) The term "adjacent to" requires a "precise, clear standard" [IAPA, §100/5-20]. None is given. Does "adjacent to" mean 6 inches, 16 inches, 6 feet, 16 feet, or 60 feet? The IDNR does not say. 4.) Frack pad pipes and equipment can become incredibly radioactive over time. The very large temperature and pressure drops, as fluids move to the surface from thousands of feet underground, means that aqueous radioactive salts precipitate out as scale on pipes and equipment. The levels of radioactivity in pipe scale can exceed 100,000 picoCuries per gram and constitute a hazard to workers, or others who are exposed to recycled scrap metal from gas and oil operations. Yet, IDNR does not call on its General Assembly deferred "Power and authority" [Act, §1-15(e)] to test pipe, tanks, sludge, and equipment. This issue has been an issue in the oil and gas industry since the 1980s. Consequences: According to studies by the Illinois State Geological Survey, the Illinois New Albany Shale Formation, the source rock for our oil and gas reserves, has above average levels of uranium (29 ppm). Uranium decays into radium and thence radon. Both uranium and radium are water soluble. As noted, the U.S. Geological Survey has found oil field brine or produced water in Southern Illinois to have Radium226 levels that average more than 1,000 picoCuries / liter (USGS 1999). That reading is 67 times above the maximum contamination level of the EPA. Radium226 has a half life of 1,600 years. Uranium228 has a half life of 4.468 billion years. If these water soluble salts leach into our aquifers, nearby communities will require--if possible--very expensive water treatment for the next 1,000 years. We may have to return to rainwater harvesting with the modern equivalent of cisterns. The radioactive levels for produced water from shale gas operations are likely to be 2 to 4 times higher than oilfield brine -- on average, 2,000 to 4,000 picoCuries per liter. In addition, radon levels in methane, propane, and ethane can be dangerously high. When it becomes commercial to extract shale gas from the SE corner of the state, major markets, such as Springfield and Chicago, will only be 0.9 and 1.4 days removed from shale gas wellheads. Even though radon222 has a half life of only 3.8 days, the closeness of major Illinois retail gas markets will mean that large number of people will be breathing in high levels of radon when they cook meals. The average level of indoor exposure to radon in Illinois is already 4.4

## Fair Economy Illinois

---

pCi/L ( American Lung Association 2013). The EPA maximum level--the point at which corrective action should be taken--is 4.0 pCi/L, and the preferred level is =3.0 pCi/L. The turn to shale gas, with its high levels of radon, will also turn a major Illinois public health problem in the wrong direction. Radioactive scale in pipe and equipment presents another problem; high levels of radioactivity have been found in school playground equipment and bleachers in school sports stadiums in Mississippi and Texas. Do we want untested oil and gas field scrap metal sold into Illinois markets? Do we want our children exposed on a daily basis to radioactive metal? The present rules creates no barriers to such an outcome. The problems cited above are why Illinois, with its large number of nuclear power plants, has a Low-Level Radioactive Waste Management Act. It and OSHA are the applicable State and Federal agencies with respect to the issue of radioactive waste and work safety standards in settings with exposure to radioactivity. If we faithfully follow applicable State and federal laws, Illinois can minimize the pernicious problems other states are going to face from the uncontrolled release of radioactive elements into their water and soil and work and non-work settings. We should prevent these problem from the start. Cleanup, after the oil and gas industry is gone, will be dreadfully expensive.. Recommendations: 1. Define the test date as = Day 21, the point at which increases in test results begin to level off. 2. Test for "radioactivity" in (1) flowback/produced water, (2) drill cuttings, soil "adjacent to" (3) storage tanks and (4) reserve pits, and (5) pipes and well pad equipment. 3. Define "adjacent to" as between 6 and 12 inches with test samples to be taken within the top 6 inches of soil 4. The rules should also require that the requirements of the Illinois Low Level Radioactivity Waste Management Act be followed.

Sincerely, Anna Woolery Chicago, IL 60637

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Act §1-75(a)7 requires radioactivity testing "once per well site" for (1) flowback water and ground "adjacent to" (2) storage tanks and (3) reserve pits. Act § 1-120 requires IDNR compliance with all "applicable federal, State, and local laws." One applicable State law is the Illinois Low-Level Radioactive Waste Management Act (PA 83-991 / 420ILCS20). Another is the Occupational Health and Safety Administration (OSHA) standards for workplace safety in settings with exposure to radioactivity (29 CFR 1910.1096). Rules §245.850(d)1-E and §245.850(e) are incomplete and deficient, and these inadequacies can "constitute a serious threat"--indeed, deadly threat-- "to the public interest, safety, or welfare" of Illinois citizens." Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Notably absent from these proposed rules is a requirement for the testing of "produced water", the fluid that returns from the well during the later stage of production (after flowback). Under the proposed rules, "produced water" can be stored on site and/or can be "recycled", yet there is no testing requirement. Naturally occurring radioactive material (NORM) is found in "produced water" also. See Technologically enhanced naturally occurring radioactive materials in the oil industry (TENORM), Nukleonika 2009; 54(1):3-9, and sources cited therein, especially for TENORM in produced water in the U.S., available at [http://www.nukleonika.pl/www/back/full/vol54\\_2009/v54n1p003f.pdf](http://www.nukleonika.pl/www/back/full/vol54_2009/v54n1p003f.pdf). See also NORM is also found on scale in oil pipes and on fracking equipment. (See Kentucky Resources Council Proposes Comprehensive Plan For Investigating Radiological Contamination In Martha Oil Field. August 11, 2005. <http://www.kyrc.org/webnewspro/112381723236086.shtml>.) IDNR's definitions of "flowback water" and "produced water" are different. DNR adequately protect workers and the general public? Elaboration: IDNR does not define a Fixed Date ( $\pm X$  days) for testing. Day 1, <Hour 1 test results will be orders of magnitude lower than either Day 2 or Day 10 tests results, and Day 10 tests results will be significantly lower than Day 80 ( $\pm 7$  days) results. Failure to specify a Fixed Test Date ( $\pm X$  days) renders test data so many irrelevant apples and oranges and allows companies to report suppressed, meaningless results by reporting Day 1, < 1 Hour data. The figure below, provided by the USGS, illustrates the nature of the problem. Please note that radium is not tested at Day 1, < 1 Hour. However, radium coprecipitates with barium, which is represented in total dissolved solids (TDS). It will therefore track TDS fairly closely. Conclusion: companies will be testing the very first flowback water to emerge from a fracked well. It will be Day 1, Minute 1 test results. 2.) There are two pits on a frack pad, one for "emergency" flowback and another, smaller one for drill cuttings and drilling mud. It is a basic principle in horizontal fracking to steer the drill bit through the horizontal strata with the highest gamma radiation readings (GAPI logs). The reason is that radioactivity correlates highly with total organic content (TOC) in the rock, and TOC correlates highly with oil and gas yields. This means that rock cuttings in the smaller drill mud and cuttings frack pit will often be more radioactive than flowback water. The IDNR knows this; yet it does not call for testing of drill bit pits as allowed under the Powers and duties section of the Act (§1- 15). 3.) The term "adjacent to" requires a "precise, clear standard" [IAPA, §100/5-20]. None is given. Does "adjacent to" mean 6 inches, 16 inches, 6 feet, 16 feet, or 60 feet? The IDNR does not say. 4.) Frack pad pipes and equipment can become incredibly radioactive over time. The very large temperature and pressure drops, as fluids move to the surface from thousands of feet underground, means that aqueous radioactive salts precipitate out as scale on pipes and equipment. The levels of radioactivity in pipe scale can exceed 100,000 picoCuries per gram and constitute a hazard to workers, or others who are exposed to recycled scrap metal from gas and oil operations. Yet, IDNR does not call on its General Assembly deferred "Power and authority" [Act, §1-15(e)] to test pipe, tanks, sludge, and equipment. This issue has been an issue in the oil and gas industry since the 1980s. Consequences: According to studies by the Illinois State Geological Survey, the Illinois New Albany Shale Formation, the source rock for our oil and gas reserves, has above average levels of uranium (29 ppm). Uranium decays into radium and thence radon. Both uranium and radium are water soluble. As noted, the U.S. Geological Survey has found oil field brine or produced water in Southern Illinois to have Radium226 levels that average more than 1,000 picoCuries / liter (USGS 1999). That reading is 67 times above the maximum contamination level of the EPA. Radium226 has a half life of 1,600 years. Uranium228 has a half life of 4.468 billion years. If these water soluble salts leach into our aquifers, nearby communities will require--if possible--very expensive water treatment for the next 1,000 years. We may have to return to rainwater harvesting with the modern equivalent of cisterns. The radioactive levels for produced water from shale gas operations are likely to be 2 to 4 times higher than oilfield brine -- on average, 2,000 to 4,000 picoCuries per liter. In addition, radon levels in methane, propane, and ethane can be dangerously high. When it becomes commercial to extract shale gas from the SE corner of the state, major markets, such as Springfield and Chicago, will only be 0.9 and 1.4 days removed from shale gas wellheads. Even though radon222 has a half life of only 3.8 days, the closeness of major Illinois retail gas markets will mean that large number of people will be breathing in high levels of radon when they cook meals. The average level of indoor exposure to radon in Illinois is already 4.4

## Fair Economy Illinois

---

pCi/L ( American Lung Association 2013). The EPA maximum level--the point at which corrective action should be taken--is 4.0 pCi/L, and the preferred level is =3.0 pCi/L. The turn to shale gas, with its high levels of radon, will also turn a major Illinois public health problem in the wrong direction. Radioactive scale in pipe and equipment presents another problem; high levels of radioactivity have been found in school playground equipment and bleachers in school sports stadiums in Mississippi and Texas. Do we want untested oil and gas field scrap metal sold into Illinois markets? Do we want our children exposed on a daily basis to radioactive metal? The present rules creates no barriers to such an outcome. The problems cited above are why Illinois, with its large number of nuclear power plants, has a Low-Level Radioactive Waste Management Act. It and OSHA are the applicable State and Federal agencies with respect to the issue of radioactive waste and work safety standards in settings with exposure to radioactivity. If we faithfully follow applicable State and federal laws, Illinois can minimize the pernicious problems other states are going to face from the uncontrolled release of radioactive elements into their water and soil and work and non-work settings. We should prevent these problem from the start. Cleanup, after the oil and gas industry is gone, will be dreadfully expensive.. Recommendations: 1. Define the test date as = Day 21, the point at which increases in test results begin to level off. 2. Test for "radioactivity" in (1) flowback/produced water, (2) drill cuttings, soil "adjacent to" (3) storage tanks and (4) reserve pits, and (5) pipes and well pad equipment. 3. Define "adjacent to" as between 6 and 12 inches with test samples to be taken within the top 6 inches of soil 4. The rules should also require that the requirements of the Illinois Low Level Radioactivity Waste Management Act be followed.

Sincerely, Brandi Madrid Chicago, IL 60640

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Act §1-75(a)7 requires radioactivity testing "once per well site" for (1) flowback water and ground "adjacent to" (2) storage tanks and (3) reserve pits. Act § 1-120 requires IDNR compliance with all "applicable federal, State, and local laws." One applicable State law is the Illinois Low-Level Radioactive Waste Management Act (PA 83-991 / 420ILCS20). Another is the Occupational Health and Safety Administration (OSHA) standards for workplace safety in settings with exposure to radioactivity (29 CFR 1910.1096). Rules §245.850(d)1-E and §245.850(e) are incomplete and deficient, and these inadequacies can "constitute a serious threat"--indeed, deadly threat-- "to the public interest, safety, or welfare" of Illinois citizens." Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Notably absent from these proposed rules is a requirement for the testing of "produced water", the fluid that returns from the well during the later stage of production (after flowback). Under the proposed rules, "produced water" can be stored on site and/or can be "recycled", yet there is no testing requirement. Naturally occurring radioactive material (NORM) is found in "produced water" also. See Technologically enhanced naturally occurring radioactive materials in the oil industry (TENORM), Nukleonika 2009; 54(1):3-9, and sources cited therein, especially for TENORM in produced water in the U.S., available at [http://www.nukleonika.pl/www/back/full/vol54\\_2009/v54n1p003f.pdf](http://www.nukleonika.pl/www/back/full/vol54_2009/v54n1p003f.pdf). See also NORM is also found on scale in oil pipes and on fracking equipment. (See Kentucky Resources Council Proposes Comprehensive Plan For Investigating Radiological Contamination In Martha Oil Field. August 11, 2005. <http://www.kyrc.org/webnewspro/112381723236086.shtml>.) IDNR's definitions of "flowback water" and "produced water" are different. The two are distinguishably different enough that they are treated as separate types of fluid by both the Hydraulic Fracturing Regulatory Act and by the DNR Rules. Discharge of produced water onto the ground or into surface water or water drainage way is prohibited but it is not tested for radioactivity. This despite the fact that this fluid will be in contact with the naturally occurring radioactive elements in the ground for a longer period than the flowback and that it is much more likely to be radioactive. Problems: Failure to test produced water for radioactivity is problematic for a variety of reasons including: The health and safety of workers on the site who will be unaware of the levels of radioactivity they are being exposed to. The health and safety of workers transporting produced water who will also be in the dark regarding the levels of radioactivity they will be exposed to. The risk of storing radioactive material in tanks not created for storing radioactive materials. The risk of "recycling" produced water—radioactivity cannot be removed by recycling. The risk to the public in transporting radioactive materials Argonne National Laboratory recently cautioned about radiological doses: "It is commonly accepted that efforts should be undertaken at all times to keep radiological doses 'as low as reasonably achievable,' which is referred to as the ALARA principle or requirement." Overview of Radiological Dose and Risk Assessment (April 2011). DNR is failing to even adequately test for radioactivity and therefore, will not know the levels of radioactivity. How, then, can

## Fair Economy Illinois

---

DNR adequately protect workers and the general public? Elaboration: IDNR does not define a Fixed Date ( $\pm X$  days) for testing. Day 1, <Hour 1 test results will be orders of magnitude lower than either Day 2 or Day 10 tests results, and Day 10 tests results will be significantly lower than Day 80 ( $\pm 7$  days) results. Failure to specify a Fixed Test Date ( $\pm X$  days) renders test data so many irrelevant apples and oranges and allows companies to report suppressed, meaningless results by reporting Day 1, < 1 Hour data. The figure below, provided by the USGS, illustrates the nature of the problem. Please note that radium is not tested at Day 1, < 1 Hour. However, radium coprecipitates with barium, which is represented in total dissolved solids (TDS). It will therefore track TDS fairly closely. Conclusion: companies will be testing the very first flowback water to emerge from a fracked well. It will be Day 1, Minute 1 test results. 2.) There are two pits on a frack pad, one for "emergency" flowback and another, smaller one for drill cuttings and drilling mud. It is a basic principle in horizontal fracking to steer the drill bit through the horizontal strata with the highest gamma radiation readings (GAPI logs). The reason is that radioactivity correlates highly with total organic content (TOC) in the rock, and TOC correlates highly with oil and gas yields. This means that rock cuttings in the smaller drill mud and cuttings frack pit will often be more radioactive than flowback water. Overview of Radiological Dose and Risk Assessment (April 2011). DNR is failing to even adequately test for radioactivity and therefore, will not know the levels of radioactivity. How, then, can

## Fair Economy Illinois

---

DNR adequately protect workers and the general public? Elaboration: IDNR does not define a Fixed Date ( $\pm X$  days) for testing. Day 1, <Hour 1 test results will be orders of magnitude lower than either Day 2 or Day 10 tests results, and Day 10 tests results will be significantly lower than Day 80 ( $\pm 7$  days) results. Failure to specify a Fixed Test Date ( $\pm X$  days) renders test data so many irrelevant apples and oranges and allows companies to report suppressed, meaningless results by reporting Day 1, < 1 Hour data. The figure below, provided by the USGS, illustrates the nature of the problem. Please note that radium is not tested at Day 1, < 1 Hour. However, radium coprecipitates with barium, which is represented in total dissolved solids (TDS). It will therefore track TDS fairly closely. Conclusion: companies will be testing the very first flowback water to emerge from a fracked well. It will be Day 1, Minute 1 test results. 2.) There are two pits on a frack pad, one for "emergency" flowback and another, smaller one for drill cuttings and drilling mud. It is a basic principle in horizontal fracking to steer the drill bit through the horizontal strata with the highest gamma radiation readings (GAPI logs). The reason is that radioactivity correlates highly with total organic content (TOC) in the rock, and TOC correlates highly with oil and gas yields. This means that rock cuttings in the smaller drill mud and cuttings frack pit will often be more radioactive than flowback water. The IDNR knows this; yet it does not call for testing of drill bit pits as allowed under the Powers and duties section of the Act (§1- 15). 3.) The term "adjacent to" requires a "precise, clear standard" [IAPA, §100/5-20]. None is given. Does "adjacent to" mean 6 inches, 16 inches, 6 feet, 16 feet, or 60 feet? The IDNR does not say. 4.) Frack pad pipes and equipment can become incredibly radioactive over time. The very large temperature and pressure drops, as fluids move to the surface from thousands of feet underground, means that aqueous radioactive salts precipitate out as scale on pipes and equipment. The levels of radioactivity in pipe scale can exceed 100,000 picoCuries per gram and constitute a hazard to workers, or others who are exposed to recycled scrap metal from gas and oil operations. Yet, IDNR does not call on its General Assembly deferred "Power and authority" [Act, §1-15(e)] to test pipe, tanks, sludge, and equipment. This issue has been an issue in the oil and gas industry since the 1980s. Consequences: According to studies by the Illinois State Geological Survey, the Illinois New Albany Shale Formation, the source rock for our oil and gas reserves, has above average levels of uranium (29 ppm). Uranium decays into radium and thence radon. Both uranium and radium are water soluble. As noted, the U.S. Geological Survey has found oil field brine or produced water in Southern Illinois to have Radium226 levels that average more than 1,000 picoCuries / liter (USGS 1999). That reading is 67 times above the maximum contamination level of the EPA. Radium226 has a half life of 1,600 years. Uranium228 has a half life of 4.468 billion years. If these water soluble salts leach into our aquifers, nearby communities will require--if possible--very expensive water treatment for the next 1,000 years. We may have to return to rainwater harvesting with the modern equivalent of cisterns. The radioactive levels for produced water from shale gas operations are likely to be 2 to 4 times higher than oilfield brine -- on average, 2,000 to 4,000 picoCuries per liter. In addition, radon levels in methane, propane, and ethane can be dangerously high. When it becomes commercial to extract shale gas from the SE corner of the state, major markets, such as Springfield and Chicago, will only be 0.9 and 1.4 days removed from shale gas wellheads. Even though radon222 has a half life of only 3.8 days, the closeness of major Illinois retail gas markets will mean that large number of people will be breathing in high levels of radon when they cook meals. The average level of indoor exposure to radon in Illinois is already 4.4

## Fair Economy Illinois

---

pCi/L ( American Lung Association 2013). The EPA maximum level--the point at which corrective action should be taken--is 4.0 pCi/L, and the preferred level is =3.0 pCi/L. The turn to shale gas, with its high levels of radon, will also turn a major Illinois public health problem in the wrong direction. Radioactive scale in pipe and equipment presents another problem; high levels of radioactivity have been found in school playground equipment and bleachers in school sports stadiums in Mississippi and Texas. Do we want untested oil and gas field scrap metal sold into Illinois markets? Do we want our children exposed on a daily basis to radioactive metal? The present rules creates no barriers to such an outcome. The problems cited above are why Illinois, with its large number of nuclear power plants, has a Low-Level Radioactive Waste Management Act. It and OSHA are the applicable State and Federal agencies with respect to the issue of radioactive waste and work safety standards in settings with exposure to radioactivity. If we faithfully follow applicable State and federal laws, Illinois can minimize the pernicious problems other states are going to face from the uncontrolled release of radioactive elements into their water and soil and work and non-work settings. We should prevent these problem from the start. Cleanup, after the oil and gas industry is gone, will be dreadfully expensive.. Recommendations: 1. Define the test date as = Day 21, the point at which increases in test results begin to level off. 2. Test for "radioactivity" in (1) flowback/produced water, (2) drill cuttings, soil "adjacent to" (3) storage tanks and (4) reserve pits, and (5) pipes and well pad equipment. 3. Define "adjacent to" as between 6 and 12 inches with test samples to be taken within the top 6 inches of soil 4. The rules should also require that the requirements of the Illinois Low Level Radioactivity Waste Management Act be followed.

Sincerely, Bruce Ostdick Elgin, IL 60123

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Act §1-75(a)7 requires radioactivity testing "once per well site" for (1) flowback water and ground "adjacent to" (2) storage tanks and (3) reserve pits. Act § 1-120 requires IDNR compliance with all "applicable federal, State, and local laws." One applicable State law is the Illinois Low-Level Radioactive Waste Management Act (PA 83-991 / 420ILCS20). Another is the Occupational Health and Safety Administration (OSHA) standards for workplace safety in settings with exposure to radioactivity (29 CFR 1910.1096). Rules §245.850(d)1-E and §245.850(e) are incomplete and deficient, and these inadequacies can "constitute a serious threat"--indeed, deadly threat-- "to the public interest, safety, or welfare" of Illinois citizens." Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Notably absent from these proposed rules is a requirement for the testing of "produced water", the fluid that returns from the well during the later stage of production (after flowback). Under the proposed rules, "produced water" can be stored on site and/or can be "recycled", yet there is no testing requirement. Naturally occurring radioactive material (NORM) is found in "produced water" also. See Technologically enhanced naturally occurring radioactive materials in the oil industry (TENORM), Nukleonika 2009; 54(1):3-9, and sources cited therein, especially for TENORM in produced water in the U.S., available at [http://www.nukleonika.pl/www/back/full/vol54\\_2009/v54n1p003f.pdf](http://www.nukleonika.pl/www/back/full/vol54_2009/v54n1p003f.pdf). See also NORM is also found on scale in oil pipes and on fracking equipment. (See Kentucky Resources Council Proposes Comprehensive Plan For Investigating Radiological Contamination In Martha Oil Field. August 11, 2005. <http://www.kyrc.org/webnewspro/112381723236086.shtml>.) IDNR's definitions of "flowback water" and "produced water" are different. The two are distinguishably different enough that they are treated as separate types of fluid by both the Hydraulic Fracturing Regulatory Act and by the DNR Rules. Discharge of produced water onto the ground or into surface water or water drainage way is prohibited but it is not tested for radioactivity. This despite the fact that this fluid will be in contact with the naturally occurring radioactive elements in the ground for a longer period than the flowback and that it is much more likely to be radioactive. Problems: Failure to test produced water for radioactivity is problematic for a variety of reasons including: The health and safety of workers on the site who will be unaware of the levels of radioactivity they are being exposed to. The health and safety of workers transporting produced water who will also be in the dark regarding the levels of radioactivity they will be exposed to. The risk of storing radioactive material in tanks not created for storing radioactive materials. The risk of "recycling" produced water—radioactivity cannot be removed by recycling. The risk to the public in transporting radioactive materials Argonne National Laboratory recently cautioned about radiological doses: "It is commonly accepted that efforts should be undertaken at all times to keep radiological doses 'as low as reasonably achievable,' which is referred to as the ALARA principle or requirement." Overview of Radiological Dose and Risk Assessment (April 2011). DNR is failing to even adequately test for radioactivity and therefore, will not know the levels of radioactivity. How, then, can

## Fair Economy Illinois

---

DNR adequately protect workers and the general public? Elaboration: IDNR does not define a Fixed Date ( $\pm X$  days) for testing. Day 1, <Hour 1 test results will be orders of magnitude lower than either Day 2 or Day 10 tests results, and Day 10 tests results will be significantly lower than Day 80 ( $\pm 7$  days) results. Failure to specify a Fixed Test Date ( $\pm X$  days) renders test data so many irrelevant apples and oranges and allows companies to report suppressed, meaningless results by reporting Day 1, < 1 Hour data. The figure below, provided by the USGS, illustrates the nature of the problem. Please note that radium is not tested at Day 1, < 1 Hour. However, radium coprecipitates with barium, which is represented in total dissolved solids (TDS). It will therefore track TDS fairly closely. Conclusion: companies will be testing the very first flowback water to emerge from a fracked well. It will be Day 1, Minute 1 test results. 2.) There are two pits on a frack pad, one for "emergency" flowback and another, smaller one for drill cuttings and drilling mud. It is a basic principle in horizontal fracking to steer the drill bit through the horizontal strata with the highest gamma radiation readings (GAPI logs). The reason is that radioactivity correlates highly with total organic content (TOC) in the rock, and TOC correlates highly with oil and gas yields. This means that rock cuttings in the smaller drill mud and cuttings frack pit will often be more radioactive than flowback water. The IDNR knows this; yet it does not call for testing of drill bit pits as allowed under the Powers and duties section of the Act (§1- 15). 3.) The term "adjacent to" requires a "precise, clear standard" [IAPA, §100/5-20]. None is given. Does "adjacent to" mean 6 inches, 16 inches, 6 feet, 16 feet, or 60 feet? The IDNR does not say. 4.) Frack pad pipes and equipment can become incredibly radioactive over time. The very large temperature and pressure drops, as fluids move to the surface from thousands of feet underground, means that aqueous radioactive salts precipitate out as scale on pipes and equipment. The levels of radioactivity in pipe scale can exceed 100,000 picoCuries per gram and constitute a hazard to workers, or others who are exposed to recycled scrap metal from gas and oil operations. Yet, IDNR does not call on its General Assembly deferred "Power and authority" [Act, §1-15(e)] to test pipe, tanks, sludge, and equipment. This issue has been an issue in the oil and gas industry since the 1980s. Consequences: According to studies by the Illinois State Geological Survey, the Illinois New Albany Shale Formation, the source rock for our oil and gas reserves, has above average levels of uranium (29 ppm). Uranium decays into radium and thence radon. Both uranium and radium are water soluble. As noted, the U.S. Geological Survey has found oil field brine or produced water in Southern Illinois to have Radium226 levels that average more than 1,000 picoCuries / liter (USGS 1999). That reading is 67 times above the maximum contamination level of the EPA. Radium226 has a half life of 1,600 years. Uranium228 has a half life of 4.468 billion years. If these water soluble salts leach into our aquifers, nearby communities will require--if possible--very expensive water treatment for the next 1,000 years. We may have to return to rainwater harvesting with the modern equivalent of cisterns. The radioactive levels for produced water from shale gas operations are likely to be 2 to 4 times higher than oilfield brine -- on average, 2,000 to 4,000 picoCuries per liter. In addition, radon levels in methane, propane, and ethane can be dangerously high. When it becomes commercial to extract shale gas from the SE corner of the state, major markets, such as Springfield and Chicago, will only be 0.9 and 1.4 days removed from shale gas wellheads. Even though radon222 has a half life of only 3.8 days, the closeness of major Illinois retail gas markets will mean that large number of people will be breathing in high levels of radon when they cook meals. The average level of indoor exposure to radon in Illinois is already 4.4

## Fair Economy Illinois

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Act §1-75(a)7 requires radioactivity testing "once per well site" for (1) flowback water and ground "adjacent to" (2) storage tanks and (3) reserve pits. Act § 1-120 requires IDNR compliance with all "applicable federal, State, and local laws." One applicable State law is the Illinois Low-Level Radioactive Waste Management Act (PA 83-991 / 420ILCS20). Another is the Occupational Health and Safety Administration (OSHA) standards for workplace safety in settings with exposure to radioactivity (29 CFR 1910.1096). Rules §245.850(d)1-E and §245.850(e) are incomplete and deficient, and these inadequacies can "constitute a serious threat"--indeed, deadly threat-- "to the public interest, safety, or welfare" of Illinois citizens." Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Notably absent from these proposed rules is a requirement for the testing of "produced water", the fluid that returns from the well during the later stage of production (after flowback). Under the proposed rules, "produced water" can be stored on site and/or can be "recycled", yet there is no testing requirement. Naturally occurring radioactive material (NORM) is found in "produced water" also. See Technologically enhanced naturally occurring radioactive materials in the oil industry (TENORM), Nukleonika 2009; 54(1):3-9, and sources cited therein, especially for TENORM in produced water in the U.S., available at [http://www.nukleonika.pl/www/back/full/vol54\\_2009/v54n1p003f.pdf](http://www.nukleonika.pl/www/back/full/vol54_2009/v54n1p003f.pdf). See also NORM is also found on scale in oil pipes and on fracking equipment. (See Kentucky Resources Council Proposes Comprehensive Plan For Investigating Radiological Contamination In Martha Oil Field. August 11, 2005. <http://www.kyrc.org/webnewspro/112381723236086.shtml>.) IDNR's definitions of "flowback water" and "produced water" are different. The two are distinguishably different enough that they are treated as separate types of fluid by both the Hydraulic Fracturing Regulatory Act and by the DNR Rules. Discharge of produced water onto the ground or into surface water or water drainage way is prohibited but it is not tested for radioactivity. This despite the fact that this fluid will be in contact with the naturally occurring radioactive elements in the ground for a longer period than the flowback and that it is much more likely to be radioactive. Problems: Failure to test produced water for radioactivity is problematic for a variety of reasons including: The health and safety of workers on the site who will be unaware of the levels of radioactivity they are being exposed to. The health and safety of workers transporting produced water who will also be in the dark regarding the levels of radioactivity they will be exposed to. The risk of storing radioactive material in tanks not created for storing radioactive materials. The risk of "recycling" produced water—radioactivity cannot be removed by recycling. The risk to the public in transporting radioactive materials Argonne National Laboratory recently cautioned about radiological doses: "It is commonly accepted that efforts should be undertaken at all times to keep radiological doses 'as low as reasonably achievable,' which is referred to as the ALARA principle or requirement." Overview of Radiological Dose and Risk Assessment (April 2011). DNR is failing to even adequately test for radioactivity and therefore, will not know the levels of radioactivity. How, then, can

## Fair Economy Illinois

---

DNR adequately protect workers and the general public? Elaboration: IDNR does not define a Fixed Date ( $\pm X$  days) for testing. Day 1, <Hour 1 test results will be orders of magnitude lower than either Day 2 or Day 10 tests results, and Day 10 tests results will be significantly lower than Day 80 ( $\pm 7$  days) results. Failure to specify a Fixed Test Date ( $\pm X$  days) renders test data so many irrelevant apples and oranges and allows companies to report suppressed, meaningless results by reporting Day 1, < 1 Hour data. The figure below, provided by the USGS, illustrates the nature of the problem. Please note that radium is not tested at Day 1, < 1 Hour. However, radium coprecipitates with barium, which is represented in total dissolved solids (TDS). It will therefore track TDS fairly closely. Conclusion: companies will be testing the very first flowback water to emerge from a fracked well. It will be Day 1, Minute 1 test results. 2.) There are two pits on a frack pad, one for "emergency" flowback and another, smaller one for drill cuttings and drilling mud. It is a basic principle in horizontal fracking to steer the drill bit through the horizontal strata with the highest gamma radiation readings (GAPI logs). The reason is that radioactivity correlates highly with total organic content (TOC) in the rock, and TOC correlates highly with oil and gas yields. This means that rock cuttings in the smaller drill mud and cuttings frack pit will often be more radioactive than flowback water. The IDNR knows this; yet it does not call for testing of drill bit pits as allowed under the Powers and duties section of the Act (§1- 15). 3.) The term "adjacent to" requires a "precise, clear standard" [IAPA, §100/5-20]. None is given. Does "adjacent to" mean 6 inches, 16 inches, 6 feet, 16 feet, or 60 feet? The IDNR does not say. 4.) Frack pad pipes and equipment can become incredibly radioactive over time. The very large temperature and pressure drops, as fluids move to the surface from thousands of feet underground, means that aqueous radioactive salts precipitate out as scale on pipes and equipment. The levels of radioactivity in pipe scale can exceed 100,000 picoCuries per gram and constitute a hazard to workers, or others who are exposed to recycled scrap metal from gas and oil operations. Yet, IDNR does not call on its General Assembly deferred "Power and authority" [Act, §1-15(e)] to test pipe, tanks, sludge, and equipment. This issue has been an issue in the oil and gas industry since the 1980s. Consequences: According to studies by the Illinois State Geological Survey, the Illinois New Albany Shale Formation, the source rock for our oil and gas reserves, has above average levels of uranium (29 ppm). Uranium decays into radium and thence radon. Both uranium and radium are water soluble. As noted, the U.S. Geological Survey has found oil field brine or produced water in Southern Illinois to have Radium226 levels that average more than 1,000 picoCuries / liter (USGS 1999). That reading is 67 times above the maximum contamination level of the EPA. Radium226 has a half life of 1,600 years. Uranium228 has a half life of 4.468 billion years. If these water soluble salts leach into our aquifers, nearby communities will require--if possible--very expensive water treatment for the next 1,000 years. We may have to return to rainwater harvesting with the modern equivalent of cisterns. The radioactive levels for produced water from shale gas operations are likely to be 2 to 4 times higher than oilfield brine -- on average, 2,000 to 4,000 picoCuries per liter. In addition, radon levels in methane, propane, and ethane can be dangerously high. When it becomes commercial to extract shale gas from the SE corner of the state, major markets, such as Springfield and Chicago, will only be 0.9 and 1.4 days removed from shale gas wellheads. Even though radon222 has a half life of only 3.8 days, the closeness of major Illinois retail gas markets will mean that large number of people will be breathing in high levels of radon when they cook meals. The average level of indoor exposure to radon in Illinois is already 4.4

## Fair Economy Illinois

---

pCi/L ( American Lung Association 2013). The EPA maximum level--the point at which corrective action should be taken--is 4.0 pCi/L, and the preferred level is =3.0 pCi/L. The turn to shale gas, with its high levels of radon, will also turn a major Illinois public health problem in the wrong direction. Radioactive scale in pipe and equipment presents another problem; high levels of radioactivity have been found in school playground equipment and bleachers in school sports stadiums in Mississippi and Texas. Do we want untested oil and gas field scrap metal sold into Illinois markets? Do we want our children exposed on a daily basis to radioactive metal? The present rules creates no barriers to such an outcome. The problems cited above are why Illinois, with its large number of nuclear power plants, has a Low-Level Radioactive Waste Management Act. It and OSHA are the applicable State and Federal agencies with respect to the issue of radioactive waste and work safety standards in settings with exposure to radioactivity. If we faithfully follow applicable State and federal laws, Illinois can minimize the pernicious problems other states are going to face from the uncontrolled release of radioactive elements into their water and soil and work and non-work settings. We should prevent these problem from the start. Cleanup, after the oil and gas industry is gone, will be dreadfully expensive.. Recommendations: 1. Define the test date as = Day 21, the point at which increases in test results begin to level off. 2. Test for "radioactivity" in (1) flowback/produced water, (2) drill cuttings, soil "adjacent to" (3) storage tanks and (4) reserve pits, and (5) pipes and well pad equipment. 3. Define "adjacent to" as between 6 and 12 inches with test samples to be taken within the top 6 inches of soil 4. The rules should also require that the requirements of the Illinois Low Level Radioactivity Waste Management Act be followed.

Sincerely, Clara Kao Chicago, IL 60637

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Act §1-75(a)7 requires radioactivity testing "once per well site" for (1) flowback water and ground "adjacent to" (2) storage tanks and (3) reserve pits. Act § 1-120 requires IDNR compliance with all "applicable federal, State, and local laws." One applicable State law is the Illinois Low-Level Radioactive Waste Management Act (PA 83-991 / 420ILCS20). Another is the Occupational Health and Safety Administration (OSHA) standards for workplace safety in settings with exposure to radioactivity (29 CFR 1910.1096). Rules §245.850(d)1-E and §245.850(e) are incomplete and deficient, and these inadequacies can "constitute a serious threat"--indeed, deadly threat-- "to the public interest, safety, or welfare" of Illinois citizens." Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Notably absent from these proposed rules is a requirement for the testing of "produced water", the fluid that returns from the well during the later stage of production (after flowback). Under the proposed rules, "produced water" can be stored on site and/or can be "recycled", yet there is no testing requirement. Naturally occurring radioactive material (NORM) is found in "produced water" also. See Technologically enhanced naturally occurring radioactive materials in the oil industry (TENORM), Nukleonika 2009; 54(1):3-9, and sources cited therein, especially for TENORM in produced water in the U.S., available at [http://www.nukleonika.pl/www/back/full/vol54\\_2009/v54n1p003f.pdf](http://www.nukleonika.pl/www/back/full/vol54_2009/v54n1p003f.pdf). See also NORM is also found on scale in oil pipes and on fracking equipment. (See Kentucky Resources Council Proposes Comprehensive Plan For Investigating Radiological Contamination In Martha Oil Field. August 11, 2005. <http://www.kyrc.org/webnewspro/112381723236086.shtml>.) IDNR's definitions of "flowback water" and "produced water" are different. The two are distinguishably different enough that they are treated as separate types of fluid by both the Hydraulic Fracturing Regulatory Act and by the DNR Rules. Discharge of produced water onto the ground or into surface water or water drainage way is prohibited but it is not tested for radioactivity. This despite the fact that this fluid will be in contact with the naturally occurring radioactive elements in the ground for a longer period than the flowback and that it is much more likely to be radioactive. Problems: Failure to test produced water for radioactivity is problematic for a variety of reasons including: The health and safety of workers on the site who will be unaware of the levels of radioactivity they are being exposed to. The health and safety of workers transporting produced water who will also be in the dark regarding the levels of radioactivity they will be exposed to. The risk of storing radioactive material in tanks not created for storing radioactive materials. The risk of "recycling" produced water—radioactivity cannot be removed by recycling. The risk to the public in transporting radioactive materials Argonne National Laboratory recently cautioned about radiological doses: "It is commonly accepted that efforts should be undertaken at all times to keep radiological doses 'as low as reasonably achievable,' which is referred to as the ALARA principle or requirement." Overview of Radiological Dose and Risk Assessment (April 2011). DNR is failing to even adequately test for radioactivity and therefore, will not know the levels of radioactivity. How, then, can

DNR adequately protect workers and the general public? Elaboration: IDNR does not define a Fixed Date ( $\pm X$  days) for testing. Day 1, <Hour 1 test results will be orders of magnitude lower than either Day 2 or Day 10 tests results, and Day 10 tests results will be significantly lower than Day 80 ( $\pm 7$  days) results. Failure to specify a Fixed Test Date ( $\pm X$  days) renders test data so many irrelevant apples and oranges and allows companies to report suppressed, meaningless results by reporting Day 1, < 1 Hour data. The figure below, provided by the USGS, illustrates the nature of the problem. Please note that radium is not tested at Day 1, < 1 Hour. However, radium coprecipitates with barium, which is represented in total dissolved solids (TDS). It will therefore track TDS fairly closely. Conclusion: companies will be testing the very first flowback water to emerge from a fracked well. It will be Day 1, Minute 1 test results. 2.) There are two pits on a frack pad, one for "emergency" flowback and another, smaller one for drill cuttings and drilling mud. It is a basic principle in horizontal fracking to steer the drill bit through the horizontal strata with the highest gamma radiation readings (GAPI logs). The reason is that radioactivity correlates highly with total organic content (TOC) in the rock, and TOC correlates highly with oil and gas yields. This means that rock cuttings in the smaller drill mud and cuttings frack pit will often be more radioactive than flowback water. The IDNR knows this; yet it does not call for testing of drill bit pits as allowed under the Powers and duties section of the Act (§1- 15). 3.) The term "adjacent to" requires a "precise, clear standard" [IAPA, §100/5-20]. None is given. Does "adjacent to" mean 6 inches, 16 inches, 6 feet, 16 feet, or 60 feet? The IDNR does not say. 4.) Frack pad pipes and equipment can become incredibly radioactive over time. The very large temperature and pressure drops, as fluids move to the surface from thousands of feet underground, means that aqueous radioactive salts precipitate out as scale on pipes and equipment. The levels of radioactivity in pipe scale can exceed 100,000 picoCuries per gram and constitute a hazard to workers, or others who are exposed to recycled scrap metal from gas and oil operations. Yet, IDNR does not call on its General Assembly deferred "Power and authority" [Act, §1-15(e)] to test pipe, tanks, sludge, and equipment. This issue has been an issue in the oil and gas industry since the 1980s. Consequences: According to studies by the Illinois State Geological Survey, the Illinois New Albany Shale Formation, the source rock for our oil and gas reserves, has above average levels of uranium (29 ppm). Uranium decays into radium and thence radon. Both uranium and radium are water soluble. As noted, the U.S. Geological Survey has found oil field brine or produced water in Southern Illinois to have Radium226 levels that average more than 1,000 picoCuries / liter (USGS 1999). That reading is 67 times above the maximum contamination level of the EPA. Radium226 has a half life of 1,600 years. Uranium228 has a half life of 4.468 billion years. If these water soluble salts leach into our aquifers, nearby communities will require--if possible--very expensive water treatment for the next 1,000 years. We may have to return to rainwater harvesting with the modern equivalent of cisterns. The radioactive levels for produced water from shale gas operations are likely to be 2 to 4 times higher than oilfield brine -- on average, 2,000 to 4,000 picoCuries per liter. In addition, radon levels in methane, propane, and ethane can be dangerously high. When it becomes commercial to extract shale gas from the SE corner of the state, major markets, such as Springfield and Chicago, will only be 0.9 and 1.4 days removed from shale gas wellheads. Even though radon222 has a half life of only 3.8 days, the closeness of major Illinois retail gas markets will mean that large number of people will be breathing in high levels of radon when they cook meals. The average level of indoor exposure to radon in Illinois is already 4.4

## Fair Economy Illinois

---

pCi/L ( American Lung Association 2013). The EPA maximum level--the point at which corrective action should be taken--is 4.0 pCi/L, and the preferred level is =3.0 pCi/L. The turn to shale gas, with its high levels of radon, will also turn a major Illinois public health problem in the wrong direction. Radioactive scale in pipe and equipment presents another problem; high levels of radioactivity have been found in school playground equipment and bleachers in school sports stadiums in Mississippi and Texas. Do we want untested oil and gas field scrap metal sold into Illinois markets? Do we want our children exposed on a daily basis to radioactive metal? The present rules creates no barriers to such an outcome. The problems cited above are why Illinois, with its large number of nuclear power plants, has a Low-Level Radioactive Waste Management Act. It and OSHA are the applicable State and Federal agencies with respect to the issue of radioactive waste and work safety standards in settings with exposure to radioactivity. If we faithfully follow applicable State and federal laws, Illinois can minimize the pernicious problems other states are going to face from the uncontrolled release of radioactive elements into their water and soil and work and non-work settings. We should prevent these problem from the start. Cleanup, after the oil and gas industry is gone, will be dreadfully expensive.. Recommendations: 1. Define the test date as = Day 21, the point at which increases in test results begin to level off. 2. Test for "radioactivity" in (1) flowback/produced water, (2) drill cuttings, soil "adjacent to" (3) storage tanks and (4) reserve pits, and (5) pipes and well pad equipment. 3. Define "adjacent to" as between 6 and 12 inches with test samples to be taken within the top 6 inches of soil 4. The rules should also require that the requirements of the Illinois Low Level Radioactivity Waste Management Act be followed.

Sincerely, Curtis Morris Chicago, IL 60607

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Act §1-75(a)7 requires radioactivity testing "once per well site" for (1) flowback water and ground "adjacent to" (2) storage tanks and (3) reserve pits. Act § 1-120 requires IDNR compliance with all "applicable federal, State, and local laws." One applicable State law is the Illinois Low-Level Radioactive Waste Management Act (PA 83-991 / 420ILCS20). Another is the Occupational Health and Safety Administration (OSHA) standards for workplace safety in settings with exposure to radioactivity (29 CFR 1910.1096). Rules §245.850(d)1-E and §245.850(e) are incomplete and deficient, and these inadequacies can "constitute a serious threat"--indeed, deadly threat-- "to the public interest, safety, or welfare" of Illinois citizens." Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Notably absent from these proposed rules is a requirement for the testing of "produced water", the fluid that returns from the well during the later stage of production (after flowback). Under the proposed rules, "produced water" can be stored on site and/or can be "recycled", yet there is no testing requirement. Naturally occurring radioactive material (NORM) is found in "produced water" also. See Technologically enhanced naturally occurring radioactive materials in the oil industry (TENORM), Nukleonika 2009; 54(1):3-9, and sources cited therein, especially for TENORM in produced water in the U.S., available at [http://www.nukleonika.pl/www/back/full/vol54\\_2009/v54n1p003f.pdf](http://www.nukleonika.pl/www/back/full/vol54_2009/v54n1p003f.pdf). See also NORM is also found on scale in oil pipes and on fracking equipment. (See Kentucky Resources Council Proposes Comprehensive Plan For Investigating Radiological Contamination In Martha Oil Field. August 11, 2005. <http://www.kyrc.org/webnewspro/112381723236086.shtml>.) IDNR's definitions of "flowback water" and "produced water" are different. The two are distinguishably different enough that they are treated as separate types of fluid by both the Hydraulic Fracturing Regulatory Act and by the DNR Rules. Discharge of produced water onto the ground or into surface water or water drainage way is prohibited but it is not tested for radioactivity. This despite the fact that this fluid will be in contact with the naturally occurring radioactive elements in the ground for a longer period than the flowback and that it is much more likely to be radioactive. Problems: Failure to test produced water for radioactivity is problematic for a variety of reasons including: The health and safety of workers on the site who will be unaware of the levels of radioactivity they are being exposed to. The health and safety of workers transporting produced water who will also be in the dark regarding the levels of radioactivity they will be exposed to. The risk of storing radioactive material in tanks not created for storing radioactive materials. The risk of "recycling" produced water—radioactivity cannot be removed by recycling. The risk to the public in transporting radioactive materials Argonne National Laboratory recently cautioned about radiological doses: "It is commonly accepted that efforts should be undertaken at all times to keep radiological doses 'as low as reasonably achievable,' which is referred to as the ALARA principle or requirement." DNR adequately protect workers and the general public? Elaboration: IDNR does not define a Fixed Date ( $\pm X$  days) for testing. Day 1, <Hour 1 test results will be orders of magnitude lower than either Day 2 or Day 10 tests results, and Day 10 tests results will be significantly lower than Day 80 ( $\pm 7$  days) results. Failure to specify a Fixed Test Date ( $\pm X$  days) renders test data so many irrelevant apples and oranges and allows companies to report suppressed, meaningless results by reporting Day 1, < 1 Hour data. The figure below, provided by the USGS, illustrates the nature of the problem. Please note that radium is not tested at Day 1, < 1 Hour. However, radium coprecipitates with barium, which is represented in total dissolved solids (TDS). It will therefore track TDS fairly closely. Conclusion: companies will be testing the very first flowback water to emerge from a fracked well. It will be Day 1, Minute 1 test results. 2.) There are two pits on a frack pad, one for "emergency" flowback and another, smaller one for drill cuttings and drilling mud. It is a basic principle in horizontal fracking to steer the drill bit through the horizontal strata with the highest gamma radiation readings (GAPI logs). The reason is that radioactivity correlates highly with total organic content (TOC) in the rock, and TOC correlates highly with oil and gas yields. This means that rock cuttings in the smaller drill mud and cuttings frack pit will often be more radioactive than flowback water. The IDNR knows this; yet it does not call for testing of drill bit pits as allowed under the Powers and duties section of the Act (§1- 15). 3.) The term "adjacent to" requires a "precise, clear standard" [IAPA, §100/5-20]. None is given. Does "adjacent to" mean 6 inches, 16 inches, 6 feet, 16 feet, or 60 feet? The IDNR does not say. 4.) Frack pad pipes and equipment can become incredibly radioactive over time. The very large temperature and pressure drops, as fluids move to the surface from thousands of feet underground, means that aqueous radioactive salts precipitate out as scale on pipes and equipment. The levels of radioactivity in pipe scale can exceed 100,000 picoCuries per gram and constitute a hazard to workers, or others who are exposed to recycled scrap metal from gas and oil operations. Yet, IDNR does not call on its General Assembly deferred "Power and authority" [Act, §1-15(e)] to test pipe, tanks, sludge, and equipment. This issue has been an issue in the oil and gas industry since the 1980s. Consequences: According to studies by the Illinois State Geological Survey, the Illinois New Albany Shale Formation, the source rock for our oil and gas reserves, has above average levels of uranium (29 ppm). Uranium decays into radium and thence radon. Both uranium and radium are water soluble. As noted, the U.S. Geological Survey has found oil field brine or produced water in Southern Illinois to have Radium226 levels that average more than 1,000 picoCuries / liter (USGS 1999). That reading is 67 times above the maximum contamination level of the EPA. Radium226 has a half life of 1,600 years. Uranium228 has a half life of 4.468 billion years. If these water soluble salts leach into our aquifers, nearby communities will require--if possible--very expensive water treatment for the next 1,000 years. We may have to return to rainwater harvesting with the modern equivalent of cisterns. The radioactive levels for produced water from shale gas operations are likely to be 2 to 4 times higher than oilfield brine -- on average, 2,000 to 4,000 picoCuries per liter. In addition, radon levels in methane, propane, and ethane can be dangerously high. When it becomes commercial to extract shale gas from the SE corner of the state, major markets, such as Springfield and Chicago, will only be 0.9 and 1.4 days removed from shale gas wellheads. Even though radon222 has a half life of only 3.8 days, the closeness of major Illinois retail gas markets will mean that large number of people will be breathing in high levels of radon when they cook meals. The average level of indoor exposure to radon in Illinois is already 4.4

## Fair Economy Illinois

---

pCi/L ( American Lung Association 2013). The EPA maximum level--the point at which corrective action should be taken--is 4.0 pCi/L, and the preferred level is =3.0 pCi/L. The turn to shale gas, with its high levels of radon, will also turn a major Illinois public health problem in the wrong direction. Radioactive scale in pipe and equipment presents another problem; high levels of radioactivity have been found in school playground equipment and bleachers in school sports stadiums in Mississippi and Texas. Do we want untested oil and gas field scrap metal sold into Illinois markets? Do we want our children exposed on a daily basis to radioactive metal? The present rules creates no barriers to such an outcome. The problems cited above are why Illinois, with its large number of nuclear power plants, has a Low-Level Radioactive Waste Management Act. It and OSHA are the applicable State and Federal agencies with respect to the issue of radioactive waste and work safety standards in settings with exposure to radioactivity. If we faithfully follow applicable State and federal laws, Illinois can minimize the pernicious problems other states are going to face from the uncontrolled release of radioactive elements into their water and soil and work and non-work settings. We should prevent these problem from the start. Cleanup, after the oil and gas industry is gone, will be dreadfully expensive.. Recommendations: 1. Define the test date as = Day 21, the point at which increases in test results begin to level off. 2. Test for "radioactivity" in (1) flowback/produced water, (2) drill cuttings, soil "adjacent to" (3) storage tanks and (4) reserve pits, and (5) pipes and well pad equipment. 3. Define "adjacent to" as between 6 and 12 inches with test samples to be taken within the top 6 inches of soil 4. The rules should also require that the requirements of the Illinois Low Level Radioactivity Waste Management Act be followed.

Sincerely, David Klawitter Chicago, IL 60607

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Act §1-75(a)7 requires radioactivity testing "once per well site" for (1) flowback water and ground "adjacent to" (2) storage tanks and (3) reserve pits. Act § 1-120 requires IDNR compliance with all "applicable federal, State, and local laws." One applicable State law is the Illinois Low-Level Radioactive Waste Management Act (PA 83-991 / 420ILCS20). Another is the Occupational Health and Safety Administration (OSHA) standards for workplace safety in settings with exposure to radioactivity (29 CFR 1910.1096). Rules §245.850(d)1-E and §245.850(e) are incomplete and deficient, and these inadequacies can "constitute a serious threat"--indeed, deadly threat-- "to the public interest, safety, or welfare" of Illinois citizens." Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Notably absent from these proposed rules is a requirement for the testing of "produced water", the fluid that returns from the well during the later stage of production (after flowback). Under the proposed rules, "produced water" can be stored on site and/or can be "recycled", yet there is no testing requirement. Naturally occurring radioactive material (NORM) is found in "produced water" also. See Technologically enhanced naturally occurring radioactive materials in the oil industry (TENORM), Nukleonika 2009; 54(1):3-9, and sources cited therein, especially for TENORM in produced water in the U.S., available at [http://www.nukleonika.pl/www/back/full/vol54\\_2009/v54n1p003f.pdf](http://www.nukleonika.pl/www/back/full/vol54_2009/v54n1p003f.pdf). See also NORM is also found on scale in oil pipes and on fracking equipment. (See Kentucky Resources Council Proposes Comprehensive Plan For Investigating Radiological Contamination In Martha Oil Field. August 11, 2005. <http://www.kyrc.org/webnewspro/112381723236086.shtml>.) IDNR's definitions of "flowback water" and "produced water" are different. The two are distinguishably different enough that they are treated as separate types of fluid by both the Hydraulic Fracturing Regulatory Act and by the DNR Rules. Discharge of produced water onto the ground or into surface water or water drainage way is prohibited but it is not tested for radioactivity. This despite the fact that this fluid will be in contact with the naturally occurring radioactive elements in the ground for a longer period than the flowback and that it is much more likely to be radioactive. Problems: Failure to test produced water for radioactivity is problematic for a variety of reasons including: The health and safety of workers on the site who will be unaware of the levels of radioactivity they are being exposed to. The health and safety of workers transporting produced water who will also be in the dark regarding the levels of radioactivity they will be exposed to. The risk of storing radioactive material in tanks not created for storing radioactive materials. The risk of "recycling" produced water—radioactivity cannot be removed by recycling. The risk to the public in transporting radioactive materials Argonne National Laboratory recently cautioned about radiological doses: "It is commonly accepted that efforts should be undertaken at all times to keep radiological doses 'as low as reasonably achievable,' which is referred to as the ALARA principle or requirement." Overview of Radiological Dose and Risk Assessment (April 2011). DNR is failing to even adequately test for radioactivity and therefore, will not know the levels of radioactivity. How, then, can

## Fair Economy Illinois

---

DNR adequately protect workers and the general public? Elaboration: IDNR does not define a Fixed Date ( $\pm X$  days) for testing. Day 1, <Hour 1 test results will be orders of magnitude lower than either Day 2 or Day 10 tests results, and Day 10 tests results will be significantly lower than Day 80 ( $\pm 7$  days) results. Failure to specify a Fixed Test Date ( $\pm X$  days) renders test data so many irrelevant apples and oranges and allows companies to report suppressed, meaningless results by reporting Day 1, < 1 Hour data. The figure below, provided by the USGS, illustrates the nature of the problem. Please note that radium is not tested at Day 1, < 1 Hour. However, radium coprecipitates with barium, which is represented in total dissolved solids (TDS). It will therefore track TDS fairly closely. Conclusion: companies will be testing the very first flowback water to emerge from a fracked well. It will be Day 1, Minute 1 test results. 2.) There are two pits on a frack pad, one for "emergency" flowback and another, smaller one for drill cuttings and drilling mud. It is a basic principle in horizontal fracking to steer the drill bit through the horizontal strata with the highest gamma radiation readings (GAPI logs). The reason is that radioactivity correlates highly with total organic content (TOC) in the rock, and TOC correlates highly with oil and gas yields. This means that rock cuttings in the smaller drill mud and cuttings frack pit will often be more radioactive than flowback water. The IDNR knows this; yet it does not call for testing of drill bit pits as allowed under the Powers and duties section of the Act (§1- 15). 3.) The term "adjacent to" requires a "precise, clear standard" [IAPA, §100/5-20]. None is given. Does "adjacent to" mean 6 inches, 16 inches, 6 feet, 16 feet, or 60 feet? The IDNR does not say. 4.) Frack pad pipes and equipment can become incredibly radioactive over time. The very large temperature and pressure drops, as fluids move to the surface from thousands of feet underground, means that aqueous radioactive salts precipitate out as scale on pipes and equipment. The levels of radioactivity in pipe scale can exceed 100,000 picoCuries per gram and constitute a hazard to workers, or others who are exposed to recycled scrap metal from gas and oil operations. Yet, IDNR does not call on its General Assembly deferred "Power and authority" [Act, §1-15(e)] to test pipe, tanks, sludge, and equipment. This issue has been an issue in the oil and gas industry since the 1980s. Consequences: According to studies by the Illinois State Geological Survey, the Illinois New Albany Shale Formation, the source rock for our oil and gas reserves, has above average levels of uranium (29 ppm). In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Act §1-75(a)7 requires radioactivity testing "once per well site" for (1) flowback water and ground "adjacent to" (2) storage tanks and (3) reserve pits. Act § 1-120 requires IDNR compliance with all "applicable federal, State, and local laws." One applicable State law is the Illinois Low-Level Radioactive Waste Management Act (PA 83-991 / 420ILCS20). Another is the Occupational Health and Safety Administration (OSHA) standards for workplace safety in settings with exposure to radioactivity (29 CFR 1910.1096). Rules §245.850(d)1-E and §245.850(e) are incomplete and deficient, and these inadequacies can "constitute a serious threat"--indeed, deadly threat-- "to the public interest, safety, or welfare" of Illinois citizens." Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Notably absent from these proposed rules is a requirement for the testing of "produced water", the fluid that returns from the well during the later stage of production (after flowback). Under the proposed rules, "produced water" can be stored on site and/or can be "recycled", yet there is no testing requirement. Naturally occurring radioactive material (NORM) is found in "produced water" also. See Technologically enhanced naturally occurring radioactive materials in the oil industry (TENORM), Nukleonika 2009; 54(1):3-9, and sources cited therein, especially for TENORM in produced water in the U.S., available at [http://www.nukleonika.pl/www/back/full/vol54\\_2009/v54n1p003f.pdf](http://www.nukleonika.pl/www/back/full/vol54_2009/v54n1p003f.pdf). See also NORM is also found on scale in oil pipes and on fracking equipment. (See Kentucky Resources Council Proposes Comprehensive Plan For Investigating Radiological Contamination In Martha Oil Field. August 11, 2005. <http://www.kyrc.org/webnewspro/112381723236086.shtml>.) IDNR's definitions of "flowback water" and "produced water" are different. The two are distinguishably different enough that they are treated as separate types of fluid by both the Hydraulic Fracturing Regulatory Act and by the DNR Rules. Discharge of produced water onto the ground or into surface water or water drainage way is prohibited but it is not tested for radioactivity. This despite the fact that this fluid will be in contact with the naturally occurring radioactive elements in the ground for a longer period than the flowback and that it is much more likely to be radioactive. Problems: Failure to test produced water for radioactivity is problematic for a variety of reasons including: The health and safety of workers on the site who will be unaware of the levels of radioactivity they are being exposed to. The health and safety of workers transporting produced water who will also be in the dark regarding the levels of radioactivity they will be exposed to. The risk of storing radioactive material in tanks not created for storing radioactive materials. The risk of "recycling" produced water—radioactivity cannot be removed by recycling. The risk to the public in transporting radioactive materials Argonne National Laboratory recently cautioned about radiological doses: "It is commonly accepted that efforts should be undertaken at all times to keep radiological doses 'as low as reasonably achievable,' which is referred to as the ALARA principle or requirement." Overview of Radiological Dose and Risk Assessment (April 2011). DNR is failing to even adequately test for radioactivity and therefore, will not know the levels of radioactivity. How, then, can

## Fair Economy Illinois

---

DNR adequately protect workers and the general public? Elaboration: IDNR does not define a Fixed Date ( $\pm X$  days) for testing. Day 1, <Hour 1 test results will be orders of magnitude lower than either Day 2 or Day 10 tests results, and Day 10 tests results will be significantly lower than Day 80 ( $\pm 7$  days) results. Failure to specify a Fixed Test Date ( $\pm X$  days) renders test data so many irrelevant apples and oranges and allows companies to report suppressed, meaningless results by reporting Day 1, < 1 Hour data. The figure below, provided by the USGS, illustrates the nature of the problem. Please note that radium is not tested at Day 1, < 1 Hour. However, radium coprecipitates with barium, which is represented in total dissolved solids (TDS). It will therefore track TDS fairly closely. Conclusion: companies will be testing the very first flowback water to emerge from a fracked well. It will be Day 1, Minute 1 test results. 2.) There are two pits on a frack pad, one for "emergency" flowback and another, smaller one for drill cuttings and drilling mud. It is a basic principle in horizontal fracking to steer the drill bit through the horizontal strata with the highest gamma radiation readings (GAPI logs). The reason is that radioactivity correlates highly with total organic content (TOC) in the rock, and TOC correlates highly with oil and gas yields. This means that rock cuttings in the smaller drill mud and cuttings frack pit will often be more radioactive than flowback water. The IDNR knows this; yet it does not call for testing of drill bit pits as allowed under the Powers and duties section of the Act (§1- 15). 3.) The term "adjacent to" requires a "precise, clear standard" [IAPA, §100/5-20]. None is given. Does "adjacent to" mean 6 inches, 16 inches, 6 feet, 16 feet, or 60 feet? The IDNR does not say. 4.) Frack pad pipes and equipment can become incredibly radioactive over time. The very large temperature and pressure drops, as fluids move to the surface from thousands of feet underground, means that aqueous radioactive salts precipitate out as scale on pipes and equipment. The levels of radioactivity in pipe scale can exceed 100,000 picoCuries per gram and constitute a hazard to workers, or others who are exposed to recycled scrap metal from gas and oil operations. Yet, IDNR does not call on its General Assembly deferred "Power and authority" [Act, §1-15(e)] to test pipe, tanks, sludge, and equipment. This issue has been an issue in the oil and gas industry since the 1980s. Consequences: According to studies by the Illinois State Geological Survey, the Illinois New Albany Shale Formation, the source rock for our oil and gas reserves, has above average levels of uranium (29 ppm). Uranium decays into radium and thence radon. Both uranium and radium are water soluble. As noted, the U.S. Geological Survey has found oil field brine or produced water in Southern Illinois to have Radium226 levels that average more than 1,000 picoCuries / liter (USGS 1999). That reading is 67 times above the maximum contamination level of the EPA. Radium226 has a half life of 1,600 years. Uranium228 has a half life of 4.468 billion years. If these water soluble salts leach into our aquifers, nearby communities will require--if possible--very expensive water treatment for the next 1,000 years. We may have to return to rainwater harvesting with the modern equivalent of cisterns. The radioactive levels for produced water from shale gas operations are likely to be 2 to 4 times higher than oilfield brine -- on average, 2,000 to 4,000 picoCuries per liter. In addition, radon levels in methane, propane, and ethane can be dangerously high. When it becomes commercial to extract shale gas from the SE corner of the state, major markets, such as Springfield and Chicago, will only be 0.9 and 1.4 days removed from shale gas wellheads. Even though radon222 has a half life of only 3.8 days, the closeness of major Illinois retail gas markets will mean that large number of people will be breathing in high levels of radon when they cook meals. The average level of indoor exposure to radon in Illinois is already 4.4

## Fair Economy Illinois

---

pCi/L ( American Lung Association 2013). The EPA maximum level--the point at which corrective action should be taken--is 4.0 pCi/L, and the preferred level is =3.0 pCi/L. The turn to shale gas, with its high levels of radon, will also turn a major Illinois public health problem in the wrong direction. Radioactive scale in pipe and equipment presents another problem; high levels of radioactivity have been found in school playground equipment and bleachers in school sports stadiums in Mississippi and Texas. Do we want untested oil and gas field scrap metal sold into Illinois markets? Do we want our children exposed on a daily basis to radioactive metal? The present rules creates no barriers to such an outcome. The problems cited above are why Illinois, with its large number of nuclear power plants, has a Low-Level Radioactive Waste Management Act. It and OSHA are the applicable State and Federal agencies with respect to the issue of radioactive waste and work safety standards in settings with exposure to radioactivity. If we faithfully follow applicable State and federal laws, Illinois can minimize the pernicious problems other states are going to face from the uncontrolled release of radioactive elements into their water and soil and work and non-work settings. We should prevent these problem from the start. Cleanup, after the oil and gas industry is gone, will be dreadfully expensive.. Recommendations: 1. Define the test date as = Day 21, the point at which increases in test results begin to level off. 2. Test for "radioactivity" in (1) flowback/produced water, (2) drill cuttings, soil "adjacent to" (3) storage tanks and (4) reserve pits, and (5) pipes and well pad equipment. 3. Define "adjacent to" as between 6 and 12 inches with test samples to be taken within the top 6 inches of soil 4. The rules should also require that the requirements of the Illinois Low Level Radioactivity Waste Management Act be followed.

Sincerely, Donovan Snyder Snyder Chicago, IL 60605

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Act §1-75(a)7 requires radioactivity testing "once per well site" for (1) flowback water and ground "adjacent to" (2) storage tanks and (3) reserve pits. Act § 1-120 requires IDNR compliance with all "applicable federal, State, and local laws." One applicable State law is the Illinois Low-Level Radioactive Waste Management Act (PA 83-991 / 420ILCS20). Another is the Occupational Health and Safety Administration (OSHA) standards for workplace safety in settings with exposure to radioactivity (29 CFR 1910.1096). Rules §245.850(d)1-E and §245.850(e) are incomplete and deficient, and these inadequacies can "constitute a serious threat"--indeed, deadly threat-- "to the public interest, safety, or welfare" of Illinois citizens." Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Notably absent from these proposed rules is a requirement for the testing of "produced water", the fluid that returns from the well during the later stage of production (after flowback). Under the proposed rules, "produced water" can be stored on site and/or can be "recycled", yet there is no testing requirement. Naturally occurring radioactive material (NORM) is found in "produced water" also. See Technologically enhanced naturally occurring radioactive materials in the oil industry (TENORM), Nukleonika 2009; 54(1):3-9, and sources cited therein, especially for TENORM in produced water in the U.S., available at [http://www.nukleonika.pl/www/back/full/vol54\\_2009/v54n1p003f.pdf](http://www.nukleonika.pl/www/back/full/vol54_2009/v54n1p003f.pdf). See also NORM is also found on scale in oil pipes and on fracking equipment. (See Kentucky Resources Council Proposes Comprehensive Plan For Investigating Radiological Contamination In Martha Oil Field. August 11, 2005. <http://www.kyrc.org/webnewspro/112381723236086.shtml>.) IDNR's definitions of "flowback water" and "produced water" are different. The two are distinguishably different enough that they are treated as separate types of fluid by both the Hydraulic Fracturing Regulatory Act and by the DNR Rules. Discharge of produced water onto the ground or into surface water or water drainage way is prohibited but it is not tested for radioactivity. This despite the fact that this fluid will be in contact with the naturally occurring radioactive elements in the ground for a longer period than the flowback and that it is much more likely to be radioactive. Problems: Failure to test produced water for radioactivity is problematic for a variety of reasons including: The health and safety of workers on the site who will be unaware of the levels of radioactivity they are being exposed to. The health and safety of workers transporting produced water who will also be in the dark regarding the levels of radioactivity they will be exposed to. The risk of storing radioactive material in tanks not created for storing radioactive materials. The risk of "recycling" produced water—radioactivity cannot be removed by recycling. The risk to the public in transporting radioactive materials Argonne National Laboratory recently cautioned about radiological doses: "It is commonly accepted that efforts should be undertaken at all times to keep radiological doses 'as low as reasonably achievable,' which is referred to as the ALARA principle or requirement." Overview of Radiological Dose and Risk Assessment (April 2011). DNR is failing to even adequately test for radioactivity and therefore, will not know the levels of radioactivity. How, then, can

## Fair Economy Illinois

---

DNR adequately protect workers and the general public? Elaboration: IDNR does not define a Fixed Date ( $\pm X$  days) for testing. Day 1, <Hour 1 test results will be orders of magnitude lower than either Day 2 or Day 10 tests results, and Day 10 tests results will be significantly lower than Day 80 ( $\pm 7$  days) results. Failure to specify a Fixed Test Date ( $\pm X$  days) renders test data so many irrelevant apples and oranges and allows companies to report suppressed, meaningless results by reporting Day 1, < 1 Hour data. The figure below, provided by the USGS, illustrates the nature of the problem. Please note that radium is not tested at Day 1, < 1 Hour. However, radium coprecipitates with barium, which is represented in total dissolved solids (TDS). It will therefore track TDS fairly closely. Conclusion: companies will be testing the very first flowback water to emerge from a fracked well. It will be Day 1, Minute 1 test results. 2.) There are two pits on a frack pad, one for "emergency" flowback and another, smaller one for drill cuttings and drilling mud. It is a basic principle in horizontal fracking to steer the drill bit through the horizontal strata with the highest gamma radiation readings (GAPI logs). The reason is that radioactivity correlates highly with total organic content (TOC) in the rock, and TOC correlates highly with oil and gas yields. This means that rock cuttings in the smaller drill mud and cuttings frack pit will often be more radioactive than flowback water. The IDNR knows this; yet it does not call for testing of drill bit pits as allowed under the Powers and duties section of the Act (§1- 15). 3.) The term "adjacent to" requires a "precise, clear standard" [IAPA, §100/5-20]. None is given. Does "adjacent to" mean 6 inches, 16 inches, 6 feet, 16 feet, or 60 feet? The IDNR does not say. 4.) Frack pad pipes and equipment can become incredibly radioactive over time. The very large temperature and pressure drops, as fluids move to the surface from thousands of feet underground, means that aqueous radioactive salts precipitate out as scale on pipes and equipment. The levels of radioactivity in pipe scale can exceed 100,000 picoCuries per gram and constitute a hazard to workers, or others who are exposed to recycled scrap metal from gas and oil operations. Yet, IDNR does not call on its General Assembly deferred "Power and authority" [Act, §1-15(e)] to test pipe, tanks, sludge, and equipment. This issue has been an issue in the oil and gas industry since the 1980s. Consequences: According to studies by the Illinois State Geological Survey, the Illinois New Albany Shale Formation, the source rock for our oil and gas reserves, has above average levels of uranium (29 ppm). Uranium decays into radium and thence radon. Both uranium and radium are water soluble. As noted, the U.S. Geological Survey has found oil field brine or produced water in Southern Illinois to have Radium226 levels that average more than 1,000 picoCuries / liter (USGS 1999). That reading is 67 times above the maximum contamination level of the EPA. Radium226 has a half life of 1,600 years. Uranium228 has a half life of 4.468 billion years. If these water soluble salts leach into our aquifers, nearby communities will require--if possible--very expensive water treatment for the next 1,000 years. We may have to return to rainwater harvesting with the modern equivalent of cisterns. The radioactive levels for produced water from shale gas operations are likely to be 2 to 4 times higher than oilfield brine -- on average, 2,000 to 4,000 picoCuries per liter. In addition, radon levels in methane, propane, and ethane can be dangerously high. When it becomes commercial to extract shale gas from the SE corner of the state, major markets, such as Springfield and Chicago, will only be 0.9 and 1.4 days removed from shale gas wellheads. Even though radon222 has a half life of only 3.8 days, the closeness of major Illinois retail gas markets will mean that large number of people will be breathing in high levels of radon when they cook meals. The average level of indoor exposure to radon in Illinois is already 4.4

## Fair Economy Illinois

---

pCi/L ( American Lung Association 2013). The EPA maximum level--the point at which corrective action should be taken--is 4.0 pCi/L, and the preferred level is =3.0 pCi/L. The turn to shale gas, with its high levels of radon, will also turn a major Illinois public health problem in the wrong direction. Radioactive scale in pipe and equipment presents another problem; high levels of radioactivity have been found in school playground equipment and bleachers in school sports stadiums in Mississippi and Texas. Do we want untested oil and gas field scrap metal sold into Illinois markets? Do we want our children exposed on a daily basis to radioactive metal? The present rules creates no barriers to such an outcome. The problems cited above are why Illinois, with its large number of nuclear power plants, has a Low-Level Radioactive Waste Management Act. It and OSHA are the applicable State and Federal agencies with respect to the issue of radioactive waste and work safety standards in settings with exposure to radioactivity. If we faithfully follow applicable State and federal laws, Illinois can minimize the pernicious problems other states are going to face from the uncontrolled release of radioactive elements into their water and soil and work and non-work settings. We should prevent these problem from the start. Cleanup, after the oil and gas industry is gone, will be dreadfully expensive.. Recommendations: 1. Define the test date as = Day 21, the point at which increases in test results begin to level off. 2. Test for "radioactivity" in (1) flowback/produced water, (2) drill cuttings, soil "adjacent to" (3) storage tanks and (4) reserve pits, and (5) pipes and well pad equipment. 3. Define "adjacent to" as between 6 and 12 inches with test samples to be taken within the top 6 inches of soil 4. The rules should also require that the requirements of the Illinois Low Level Radioactivity Waste Management Act be followed.

Sincerely, Edith Villavicencio New York, IL 10003

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Act §1-75(a)7 requires radioactivity testing "once per well site" for (1) flowback water and ground "adjacent to" (2) storage tanks and (3) reserve pits. Act § 1-120 requires IDNR compliance with all "applicable federal, State, and local laws." One applicable State law is the Illinois Low-Level Radioactive Waste Management Act (PA 83-991 / 420ILCS20). Another is the Occupational Health and Safety Administration (OSHA) standards for workplace safety in settings with exposure to radioactivity (29 CFR 1910.1096). Rules §245.850(d)1-E and §245.850(e) are incomplete and deficient, and these inadequacies can "constitute a serious threat"--indeed, deadly threat-- "to the public interest, safety, or welfare" of Illinois citizens." Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Notably absent from these proposed rules is a requirement for the testing of "produced water", the fluid that returns from the well during the later stage of production (after flowback). Under the proposed rules, "produced water" can be stored on site and/or can be "recycled", yet there is no testing requirement. Naturally occurring radioactive material (NORM) is found in "produced water" also. See Technologically enhanced naturally occurring radioactive materials in the oil industry (TENORM), Nukleonika 2009; 54(1):3-9, and sources cited therein, especially for TENORM in produced water in the U.S., available at [http://www.nukleonika.pl/www/back/full/vol54\\_2009/v54n1p003f.pdf](http://www.nukleonika.pl/www/back/full/vol54_2009/v54n1p003f.pdf). See also NORM is also found on scale in oil pipes and on fracking equipment. (See Kentucky Resources Council Proposes Comprehensive Plan For Investigating Radiological Contamination In Martha Oil Field. August 11, 2005. <http://www.kyrc.org/webnewspro/112381723236086.shtml>.) IDNR's definitions of "flowback water" and "produced water" are different. The two are distinguishably different enough that they are treated as separate types of fluid by both the Hydraulic Fracturing Regulatory Act and by the DNR Rules. Discharge of produced water onto the ground or into surface water or water drainage way is prohibited but it is not tested for radioactivity. There are two pits on a frack pad, one for "emergency" flowback and another, smaller one for drill cuttings and drilling mud. It is a basic principle in horizontal fracking to steer the drill bit through the horizontal strata with the highest gamma radiation readings (GAPI logs). The reason is that radioactivity correlates highly with total organic content (TOC) in the rock, and TOC correlates highly with oil and gas yields. This means that rock cuttings in the smaller drill mud and cuttings frack pit will often be more radioactive than flowback water. The IDNR knows this; yet it does not call for testing of drill bit pits as allowed under the Powers and duties section of the Act (§1- 15). 3.) The term "adjacent to" requires a "precise, clear standard" [IAPA, §100/5-20]. None is given. Does "adjacent to" mean 6 inches, 16 inches, 6 feet, 16 feet, or 60 feet? The IDNR does not say. 4.) Frack pad pipes and equipment can become incredibly radioactive over time. The very large temperature and pressure drops, as fluids move to the surface from thousands of feet underground, means that aqueous radioactive salts precipitate out as scale on pipes and equipment. The levels of radioactivity in pipe scale can exceed 100,000 picoCuries per gram and constitute a hazard to workers, or others who are exposed to recycled scrap metal from gas and oil operations. Yet, IDNR does not call on its General Assembly deferred "Power and authority" [Act, §1-15(e)] to test pipe, tanks, sludge, and equipment. This issue has been an issue in the oil and gas industry since the 1980s. Consequences: According to studies by the Illinois State Geological Survey, the Illinois New Albany Shale Formation, the source rock for our oil and gas reserves, has above average levels of uranium (29 ppm). Uranium decays into radium and thence radon. Both uranium and radium are water soluble. As noted, the U.S. Geological Survey has found oil field brine or produced water in Southern Illinois to have Radium226 levels that average more than 1,000 picoCuries / liter (USGS 1999). That reading is 67 times above the maximum contamination level of the EPA. Radium226 has a half life of 1,600 years. Uranium228 has a half life of 4.468 billion years. If these water soluble salts leach into our aquifers, nearby communities will require--if possible--very expensive water treatment for the next 1,000 years. We may have to return to rainwater harvesting with the modern equivalent of cisterns. The radioactive levels for produced water from shale gas operations are likely to be 2 to 4 times higher than oilfield brine -- on average, 2,000 to 4,000 picoCuries per liter. In addition, radon levels in methane, propane, and ethane can be dangerously high. When it becomes commercial to extract shale gas from the SE corner of the state, major markets, such as Springfield and Chicago, will only be 0.9 and 1.4 days removed from shale gas wellheads. Even though radon222 has a half life of only 3.8 days, the closeness of major Illinois retail gas markets will mean that large number of people will be breathing in high levels of radon when they cook meals. The average level of indoor exposure to radon in Illinois is already 4.4

## Fair Economy Illinois

---

pCi/L ( American Lung Association 2013). The EPA maximum level--the point at which corrective action should be taken--is 4.0 pCi/L, and the preferred level is =3.0 pCi/L. The turn to shale gas, with its high levels of radon, will also turn a major Illinois public health problem in the wrong direction. Radioactive scale in pipe and equipment presents another problem; high levels of radioactivity have been found in school playground equipment and bleachers in school sports stadiums in Mississippi and Texas. Do we want untested oil and gas field scrap metal sold into Illinois markets? Do we want our children exposed on a daily basis to radioactive metal? The present rules creates no barriers to such an outcome. The problems cited above are why Illinois, with its large number of nuclear power plants, has a Low-Level Radioactive Waste Management Act. It and OSHA are the applicable State and Federal agencies with respect to the issue of radioactive waste and work safety standards in settings with exposure to radioactivity. If we faithfully follow applicable State and federal laws, Illinois can minimize the pernicious problems other states are going to face from the uncontrolled release of radioactive elements into their water and soil and work and non-work settings. We should prevent these problem from the start. Cleanup, after the oil and gas industry is gone, will be dreadfully expensive.. Recommendations: 1. Define the test date as = Day 21, the point at which increases in test results begin to level off. 2. Test for "radioactivity" in (1) flowback/produced water, (2) drill cuttings, soil "adjacent to" (3) storage tanks and (4) reserve pits, and (5) pipes and well pad equipment. 3. Define "adjacent to" as between 6 and 12 inches with test samples to be taken within the top 6 inches of soil 4. The rules should also require that the requirements of the Illinois Low Level Radioactivity Waste Management Act be followed.

Sincerely, Florence Elgin, IL 60123

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Act §1-75(a)7 requires radioactivity testing "once per well site" for (1) flowback water and ground "adjacent to" (2) storage tanks and (3) reserve pits. Act § 1-120 requires IDNR compliance with all "applicable federal, State, and local laws." One applicable State law is the Illinois Low-Level Radioactive Waste Management Act (PA 83-991 / 420ILCS20). Another is the Occupational Health and Safety Administration (OSHA) standards for workplace safety in settings with exposure to radioactivity (29 CFR 1910.1096). Rules §245.850(d)1-E and §245.850(e) are incomplete and deficient, and these inadequacies can "constitute a serious threat"--indeed, deadly threat-- "to the public interest, safety, or welfare" of Illinois citizens." Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Notably absent from these proposed rules is a requirement for the testing of "produced water", the fluid that returns from the well during the later stage of production (after flowback). Under the proposed rules, "produced water" can be stored on site and/or can be "recycled", yet there is no testing requirement. Naturally occurring radioactive material (NORM) is found in "produced water" also. See Technologically enhanced naturally occurring radioactive materials in the oil industry (TENORM), Nukleonika 2009; 54(1):3-9, and sources cited therein, especially for TENORM in produced water in the U.S., available at [http://www.nukleonika.pl/www/back/full/vol54\\_2009/v54n1p003f.pdf](http://www.nukleonika.pl/www/back/full/vol54_2009/v54n1p003f.pdf). See also NORM is also found on scale in oil pipes and on fracking equipment. (See Kentucky Resources Council Proposes Comprehensive Plan For Investigating Radiological Contamination In Martha Oil Field. August 11, 2005. <http://www.kyrc.org/webnewspro/112381723236086.shtml>.) IDNR's definitions of "flowback water" and "produced water" are different. The two are distinguishably different enough that they are treated as separate types of fluid by both the Hydraulic Fracturing Regulatory Act and by the DNR Rules. Discharge of produced water onto the ground or into surface water or water drainage way is prohibited but it is not tested for radioactivity. This despite the fact that this fluid will be in contact with the naturally occurring radioactive elements in the ground for a longer period than the flowback and that it is much more likely to be radioactive. Problems: Failure to test produced water for radioactivity is problematic for a variety of reasons including: The health and safety of workers on the site who will be unaware of the levels of radioactivity they are being exposed to. The health and safety of workers transporting produced water who will also be in the dark regarding the levels of radioactivity they will be exposed to. The risk of storing radioactive material in tanks not created for storing radioactive materials. The risk of "recycling" produced water—radioactivity cannot be removed by recycling. The risk to the public in transporting radioactive materials Argonne National Laboratory recently cautioned about radiological doses: "It is commonly accepted that efforts should be undertaken at all times to keep radiological doses 'as low as reasonably achievable,' which is referred to as the ALARA principle or requirement." Overview of Radiological Dose and Risk Assessment (April 2011). DNR is failing to even adequately test for radioactivity and therefore, will not know the levels of radioactivity. How, then, can

## Fair Economy Illinois

---

DNR adequately protect workers and the general public? Elaboration: IDNR does not define a Fixed Date ( $\pm X$  days) for testing. Day 1, <Hour 1 test results will be orders of magnitude lower than either Day 2 or Day 10 tests results, and Day 10 tests results will be significantly lower than Day 80 ( $\pm 7$  days) results. Failure to specify a Fixed Test Date ( $\pm X$  days) renders test data so many irrelevant apples and oranges and allows companies to report suppressed, meaningless results by reporting Day 1, < 1 Hour data. The figure below, provided by the USGS, illustrates the nature of the problem. Please note that radium is not tested at Day 1, < 1 Hour. However, radium coprecipitates with barium, which is represented in total dissolved solids (TDS). It will therefore track TDS fairly closely. Conclusion: companies will be testing the very first flowback water to emerge from a fracked well. It will be Day 1, Minute 1 test results. 2.) There are two pits on a frack pad, one for "emergency" flowback and another, smaller one for drill cuttings and drilling mud. It is a basic principle in horizontal fracking to steer the drill bit through the horizontal strata with the highest gamma radiation readings (GAPI logs). The reason is that radioactivity correlates highly with total organic content (TOC) in the rock, and TOC correlates highly with oil and gas yields. This means that rock cuttings in the smaller drill mud and cuttings frack pit will often be more radioactive than flowback water. The IDNR knows this; yet it does not call for testing of drill bit pits as allowed under the Powers and duties section of the Act (§1- 15). 3.) The term "adjacent to" requires a "precise, clear standard" [IAPA, §100/5-20]. None is given. Does "adjacent to" mean 6 inches, 16 inches, 6 feet, 16 feet, or 60 feet? The IDNR does not say. 4.) Frack pad pipes and equipment can become incredibly radioactive over time. The very large temperature and pressure drops, as fluids move to the surface from thousands of feet underground, means that aqueous radioactive salts precipitate out as scale on pipes and equipment. The levels of radioactivity in pipe scale can exceed 100,000 picoCuries per gram and constitute a hazard to workers, or others who are exposed to recycled scrap metal from gas and oil operations. pCi/L ( American Lung Association 2013). The EPA maximum level--the point at which corrective action should be taken--is 4.0 pCi/L, and the preferred level is =3.0 pCi/L. The turn to shale gas, with its high levels of radon, will also turn a major Illinois public health problem in the wrong direction. Radioactive scale in pipe and equipment presents another problem; high levels of radioactivity have been found in school playground equipment and bleachers in school sports stadiums in Mississippi and Texas. Do we want untested oil and gas field scrap metal sold into Illinois markets? Do we want our children exposed on a daily basis to radioactive metal? The present rules creates no barriers to such an outcome. The problems cited above are why Illinois, with its large number of nuclear power plants, has a Low-Level Radioactive Waste Management Act. It and OSHA are the applicable State and Federal agencies with respect to the issue of radioactive waste and work safety standards in settings with exposure to radioactivity. If we faithfully follow applicable State and federal laws, Illinois can minimize the pernicious problems other states are going to face from the uncontrolled release of radioactive elements into their water and soil and work and non-work settings. We should prevent these problem from the start. Cleanup, after the oil and gas industry is gone, will be dreadfully expensive.. Recommendations: 1. Define the test date as = Day 21, the point at which increases in test results begin to level off. 2. Test for "radioactivity" in (1) flowback/produced water, (2) drill cuttings, soil "adjacent to" (3) storage tanks and (4) reserve pits, and (5) pipes and well pad equipment. 3. Define "adjacent to" as between 6 and 12 inches with test samples to be taken within the top 6 inches of soil 4. The rules should also require that the requirements of the Illinois Low Level Radioactivity Waste Management Act be followed.

Sincerely, France's Hoffman Chicago, IL 60657

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Act §1-75(a)7 requires radioactivity testing "once per well site" for (1) flowback water and ground "adjacent to" (2) storage tanks and (3) reserve pits. Act § 1-120 requires IDNR compliance with all "applicable federal, State, and local laws." One applicable State law is the Illinois Low-Level Radioactive Waste Management Act (PA 83-991 / 420ILCS20). Another is the Occupational Health and Safety Administration (OSHA) standards for workplace safety in settings with exposure to radioactivity (29 CFR 1910.1096). Rules §245.850(d)1-E and §245.850(e) are incomplete and deficient, and these inadequacies can "constitute a serious threat"--indeed, deadly threat-- "to the public interest, safety, or welfare" of Illinois citizens." Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Notably absent from these proposed rules is a requirement for the testing of "produced water", the fluid that returns from the well during the later stage of production (after flowback). Under the proposed rules, "produced water" can be stored on site and/or can be "recycled", yet there is no testing requirement. Naturally occurring radioactive material (NORM) is found in "produced water" also. See Technologically enhanced naturally occurring radioactive materials in the oil industry (TENORM), Nukleonika 2009; 54(1):3-9, and sources cited therein, especially for TENORM in produced water in the U.S., available at [http://www.nukleonika.pl/www/back/full/vol54\\_2009/v54n1p003f.pdf](http://www.nukleonika.pl/www/back/full/vol54_2009/v54n1p003f.pdf). See also NORM is also found on scale in oil pipes and on fracking equipment. (See Kentucky Resources Council Proposes Comprehensive Plan For Investigating Radiological Contamination In Martha Oil Field. August 11, 2005. <http://www.kyrc.org/webnewspro/112381723236086.shtml>.) IDNR's definitions of "flowback water" and "produced water" are different. The two are distinguishably different enough that they are treated as separate types of fluid by both the Hydraulic Fracturing Regulatory Act and by the DNR Rules. Discharge of produced water onto the ground or into surface water or water drainage way is prohibited but it is not tested for radioactivity. This despite the fact that this fluid will be in contact with the naturally occurring radioactive elements in the ground for a longer period than the flowback and that it is much more likely to be radioactive. Problems: Failure to test produced water for radioactivity is problematic for a variety of reasons including: The health and safety of workers on the site who will be unaware of the levels of radioactivity they are being exposed to. The health and safety of workers transporting produced water who will also be in the dark regarding the levels of radioactivity they will be exposed to. The risk of storing radioactive material in tanks not created for storing radioactive materials. The risk of "recycling" produced water—radioactivity cannot be removed by recycling. The risk to the public in transporting radioactive materials Argonne National Laboratory recently cautioned about radiological doses: "It is commonly accepted that efforts should be undertaken at all times to keep radiological doses 'as low as reasonably achievable,' which is referred to as the ALARA principle or requirement." Overview of Radiological Dose and Risk Assessment (April 2011). DNR is failing to even adequately test for radioactivity and therefore, will not know the levels of radioactivity. How, then, can

## Fair Economy Illinois

---

DNR adequately protect workers and the general public? Elaboration: IDNR does not define a Fixed Date ( $\pm X$  days) for testing. Day 1, <Hour 1 test results will be orders of magnitude lower than either Day 2 or Day 10 tests results, and Day 10 tests results will be significantly lower than Day 80 ( $\pm 7$  days) results. Failure to specify a Fixed Test Date ( $\pm X$  days) renders test data so many irrelevant apples and oranges and allows companies to report suppressed, meaningless results by reporting Day 1, < 1 Hour data. The figure below, provided by the USGS, illustrates the nature of the problem. Please note that radium is not tested at Day 1, < 1 Hour. However, radium coprecipitates with barium, which is represented in total dissolved solids (TDS). It will therefore track TDS fairly closely. Conclusion: companies will be testing the very first flowback water to emerge from a fracked well. It will be Day 1, Minute 1 test results. 2.) There are two pits on a frack pad, one for "emergency" flowback and another, smaller one for drill cuttings and drilling mud. It is a basic principle in horizontal fracking to steer the drill bit through the horizontal strata with the highest gamma radiation readings (GAPI logs). The reason is that radioactivity correlates highly with total organic content (TOC) in the rock, and TOC correlates highly with oil and gas yields. This means that rock cuttings in the smaller drill mud and cuttings frack pit will often be more radioactive than flowback water. The IDNR knows this; yet it does not call for testing of drill bit pits as allowed under the Powers and duties section of the Act (§1- 15). 3.) The term "adjacent to" requires a "precise, clear standard" [IAPA, §100/5-20]. None is given. Does "adjacent to" mean 6 inches, 16 inches, 6 feet, 16 feet, or 60 feet? The IDNR does not say. 4.) Frack pad pipes and equipment can become incredibly radioactive over time. The very large temperature and pressure drops, as fluids move to the surface from thousands of feet underground, means that aqueous radioactive salts precipitate out as scale on pipes and equipment. The levels of radioactivity in pipe scale can exceed 100,000 picoCuries per gram and constitute a hazard to workers, or others who are exposed to recycled scrap metal from gas and oil operations. Yet, IDNR does not call on its General Assembly deferred "Power and authority" [Act, §1-15(e)] to test pipe, tanks, sludge, and equipment. This issue has been an issue in the oil and gas industry since the 1980s. Consequences: According to studies by the Illinois State Geological Survey, the Illinois New Albany Shale Formation, the source rock for our oil and gas reserves, has above average levels of uranium (29 ppm). Uranium decays into radium and thence radon. Both uranium and radium are water soluble. As noted, the U.S. Geological Survey has found oil field brine or produced water in Southern Illinois to have Radium226 levels that average more than 1,000 picoCuries / liter (USGS 1999). That reading is 67 times above the maximum contamination level of the EPA. Radium226 has a half life of 1,600 years. Uranium228 has a half life of 4.468 billion years. If these water soluble salts leach into our aquifers, nearby communities will require--if possible--very expensive water treatment for the next 1,000 years. We may have to return to rainwater harvesting with the modern equivalent of cisterns. The radioactive levels for produced water from shale gas operations are likely to be 2 to 4 times higher than oilfield brine -- on average, 2,000 to 4,000 picoCuries per liter. In addition, radon levels in methane, propane, and ethane can be dangerously high. When it becomes commercial to extract shale gas from the SE corner of the state, major markets, such as Springfield and Chicago, will only be 0.9 and 1.4 days removed from shale gas wellheads. Even though radon222 has a half life of only 3.8 days, the closeness of major Illinois retail gas markets will mean that large number of people will be breathing in high levels of radon when they cook meals. The average level of indoor exposure to radon in Illinois is already 4.4

## Fair Economy Illinois

---

pCi/L ( American Lung Association 2013). The EPA maximum level--the point at which corrective action should be taken--is 4.0 pCi/L, and the preferred level is =3.0 pCi/L. The turn to shale gas, with its high levels of radon, will also turn a major Illinois public health problem in the wrong direction. Radioactive scale in pipe and equipment presents another problem; high levels of radioactivity have been found in school playground equipment and bleachers in school sports stadiums in Mississippi and Texas. Do we want untested oil and gas field scrap metal sold into Illinois markets? Do we want our children exposed on a daily basis to radioactive metal? The present rules creates no barriers to such an outcome. The problems cited above are why Illinois, with its large number of nuclear power plants, has a Low-Level Radioactive Waste Management Act. In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Act §1-75(a)7 requires radioactivity testing "once per well site" for (1) flowback water and ground "adjacent to" (2) storage tanks and (3) reserve pits. Act § 1-120 requires IDNR compliance with all "applicable federal, State, and local laws." One applicable State law is the Illinois Low-Level Radioactive Waste Management Act (PA 83-991 / 420ILCS20). Another is the Occupational Health and Safety Administration (OSHA) standards for workplace safety in settings with exposure to radioactivity (29 CFR 1910.1096). Rules §245.850(d)1-E and §245.850(e) are incomplete and deficient, and these inadequacies can "constitute a serious threat"--indeed, deadly threat-- "to the public interest, safety, or welfare" of Illinois citizens." Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Notably absent from these proposed rules is a requirement for the testing of "produced water", the fluid that returns from the well during the later stage of production (after flowback). Under the proposed rules, "produced water" can be stored on site and/or can be "recycled", yet there is no testing requirement. Naturally occurring radioactive material (NORM) is found in "produced water" also. See Technologically enhanced naturally occurring radioactive materials in the oil industry (TENORM), Nukleonika 2009; 54(1):3-9, and sources cited therein, especially for TENORM in produced water in the U.S., available at [http://www.nukleonika.pl/www/back/full/vol54\\_2009/v54n1p003f.pdf](http://www.nukleonika.pl/www/back/full/vol54_2009/v54n1p003f.pdf). See also NORM is also found on scale in oil pipes and on fracking equipment. (See Kentucky Resources Council Proposes Comprehensive Plan For Investigating Radiological Contamination In Martha Oil Field. August 11, 2005. <http://www.kyrc.org/webnewspro/112381723236086.shtml>.) IDNR's definitions of "flowback water" and "produced water" are different. The two are distinguishably different enough that they are treated as separate types of fluid by both the Hydraulic Fracturing Regulatory Act and by the DNR Rules. Discharge of produced water onto the ground or into surface water or water drainage way is prohibited but it is not tested for radioactivity. This despite the fact that this fluid will be in contact with the naturally occurring radioactive elements in the ground for a longer period than the flowback and that it is much more likely to be radioactive. Problems: Failure to test produced water for radioactivity is problematic for a variety of reasons including: The health and safety of workers on the site who will be unaware of the levels of radioactivity they are being exposed to. The health and safety of workers transporting produced water who will also be in the dark regarding the levels of radioactivity they will be exposed to. The risk of storing radioactive material in tanks not created for storing radioactive materials. The risk of "recycling" produced water—radioactivity cannot be removed by recycling. The risk to the public in transporting radioactive materials Argonne National Laboratory recently cautioned about radiological doses: "It is commonly accepted that efforts should be undertaken at all times to keep radiological doses 'as low as reasonably achievable,' which is referred to as the ALARA principle or requirement." Overview of Radiological Dose and Risk Assessment (April 2011). DNR is failing to even adequately test for radioactivity and therefore, will not know the levels of radioactivity. How, then, can

## Fair Economy Illinois

---

DNR adequately protect workers and the general public? Elaboration: IDNR does not define a Fixed Date ( $\pm X$  days) for testing. Day 1, <Hour 1 test results will be orders of magnitude lower than either Day 2 or Day 10 tests results, and Day 10 tests results will be significantly lower than Day 80 ( $\pm 7$  days) results. Failure to specify a Fixed Test Date ( $\pm X$  days) renders test data so many irrelevant apples and oranges and allows companies to report suppressed, meaningless results by reporting Day 1, < 1 Hour data. The figure below, provided by the USGS, illustrates the nature of the problem. Please note that radium is not tested at Day 1, < 1 Hour. However, radium coprecipitates with barium, which is represented in total dissolved solids (TDS). It will therefore track TDS fairly closely. Conclusion: companies will be testing the very first flowback water to emerge from a fracked well. It will be Day 1, Minute 1 test results. 2.) There are two pits on a frack pad, one for "emergency" flowback and another, smaller one for drill cuttings and drilling mud. It is a basic principle in horizontal fracking to steer the drill bit through the horizontal strata with the highest gamma radiation readings (GAPI logs). The reason is that radioactivity correlates highly with total organic content (TOC) in the rock, and TOC correlates highly with oil and gas yields. This means that rock cuttings in the smaller drill mud and cuttings frack pit will often be more radioactive than flowback water. The IDNR knows this; yet it does not call for testing of drill bit pits as allowed under the Powers and duties section of the Act (§1- 15). 3.) The term "adjacent to" requires a "precise, clear standard" [IAPA, §100/5-20]. None is given. Does "adjacent to" mean 6 inches, 16 inches, 6 feet, 16 feet, or 60 feet? The IDNR does not say. 4.) Frack pad pipes and equipment can become incredibly radioactive over time. The very large temperature and pressure drops, as fluids move to the surface from thousands of feet underground, means that aqueous radioactive salts precipitate out as scale on pipes and equipment. The levels of radioactivity in pipe scale can exceed 100,000 picoCuries per gram and constitute a hazard to workers, or others who are exposed to recycled scrap metal from gas and oil operations. Yet, IDNR does not call on its General Assembly deferred "Power and authority" [Act, §1-15(e)] to test pipe, tanks, sludge, and equipment. This issue has been an issue in the oil and gas industry since the 1980s. Consequences: According to studies by the Illinois State Geological Survey, the Illinois New Albany Shale Formation, the source rock for our oil and gas reserves, has above average levels of uranium (29 ppm). Uranium decays into radium and thence radon. Both uranium and radium are water soluble. As noted, the U.S. Geological Survey has found oil field brine or produced water in Southern Illinois to have Radium226 levels that average more than 1,000 picoCuries / liter (USGS 1999). That reading is 67 times above the maximum contamination level of the EPA. Radium226 has a half life of 1,600 years. Uranium228 has a half life of 4.468 billion years. If these water soluble salts leach into our aquifers, nearby communities will require--if possible--very expensive water treatment for the next 1,000 years. We may have to return to rainwater harvesting with the modern equivalent of cisterns. The radioactive levels for produced water from shale gas operations are likely to be 2 to 4 times higher than oilfield brine -- on average, 2,000 to 4,000 picoCuries per liter. In addition, radon levels in methane, propane, and ethane can be dangerously high. When it becomes commercial to extract shale gas from the SE corner of the state, major markets, such as Springfield and Chicago, will only be 0.9 and 1.4 days removed from shale gas wellheads. Even though radon222 has a half life of only 3.8 days, the closeness of major Illinois retail gas markets will mean that large number of people will be breathing in high levels of radon when they cook meals. The average level of indoor exposure to radon in Illinois is already 4.4

## Fair Economy Illinois

---

pCi/L ( American Lung Association 2013). The EPA maximum level--the point at which corrective action should be taken--is 4.0 pCi/L, and the preferred level is =3.0 pCi/L. The turn to shale gas, with its high levels of radon, will also turn a major Illinois public health problem in the wrong direction. Radioactive scale in pipe and equipment presents another problem; high levels of radioactivity have been found in school playground equipment and bleachers in school sports stadiums in Mississippi and Texas. Do we want untested oil and gas field scrap metal sold into Illinois markets? Do we want our children exposed on a daily basis to radioactive metal? The present rules creates no barriers to such an outcome. The problems cited above are why Illinois, with its large number of nuclear power plants, has a Low-Level Radioactive Waste Management Act. It and OSHA are the applicable State and Federal agencies with respect to the issue of radioactive waste and work safety standards in settings with exposure to radioactivity. If we faithfully follow applicable State and federal laws, Illinois can minimize the pernicious problems other states are going to face from the uncontrolled release of radioactive elements into their water and soil and work and non-work settings. We should prevent these problem from the start. Cleanup, after the oil and gas industry is gone, will be dreadfully expensive.. Recommendations: 1. Define the test date as = Day 21, the point at which increases in test results begin to level off. 2. Test for "radioactivity" in (1) flowback/produced water, (2) drill cuttings, soil "adjacent to" (3) storage tanks and (4) reserve pits, and (5) pipes and well pad equipment. 3. Define "adjacent to" as between 6 and 12 inches with test samples to be taken within the top 6 inches of soil 4. The rules should also require that the requirements of the Illinois Low Level Radioactivity Waste Management Act be followed.

Sincerely, Francisco Spaulding Chicago, IL 60637

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Act §1-75(a)7 requires radioactivity testing "once per well site" for (1) flowback water and ground "adjacent to" (2) storage tanks and (3) reserve pits. Act § 1-120 requires IDNR compliance with all "applicable federal, State, and local laws." One applicable State law is the Illinois Low-Level Radioactive Waste Management Act (PA 83-991 / 420ILCS20). Another is the Occupational Health and Safety Administration (OSHA) standards for workplace safety in settings with exposure to radioactivity (29 CFR 1910.1096). Rules §245.850(d)1-E and §245.850(e) are incomplete and deficient, and these inadequacies can "constitute a serious threat"--indeed, deadly threat-- "to the public interest, safety, or welfare" of Illinois citizens." Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Notably absent from these proposed rules is a requirement for the testing of "produced water", the fluid that returns from the well during the later stage of production (after flowback). Under the proposed rules, "produced water" can be stored on site and/or can be "recycled", yet there is no testing requirement. Naturally occurring radioactive material (NORM) is found in "produced water" also. See Technologically enhanced naturally occurring radioactive materials in the oil industry (TENORM), Nukleonika 2009; 54(1):3-9, and sources cited therein, especially for TENORM in produced water in the U.S., available at [http://www.nukleonika.pl/www/back/full/vol54\\_2009/v54n1p003f.pdf](http://www.nukleonika.pl/www/back/full/vol54_2009/v54n1p003f.pdf). See also NORM is also found on scale in oil pipes and on fracking equipment. (See Kentucky Resources Council Proposes Comprehensive Plan For Investigating Radiological Contamination In Martha Oil Field. August 11, 2005. <http://www.kyrc.org/webnewspro/112381723236086.shtml>.) IDNR's definitions of "flowback water" and "produced water" are different. DNR adequately protect workers and the general public? Elaboration: IDNR does not define a Fixed Date ( $\pm X$  days) for testing. Day 1, <Hour 1 test results will be orders of magnitude lower than either Day 2 or Day 10 tests results, and Day 10 tests results will be significantly lower than Day 80 ( $\pm 7$  days) results. Failure to specify a Fixed Test Date ( $\pm X$  days) renders test data so many irrelevant apples and oranges and allows companies to report suppressed, meaningless results by reporting Day 1, < 1 Hour data. The figure below, provided by the USGS, illustrates the nature of the problem. Please note that radium is not tested at Day 1, < 1 Hour. However, radium coprecipitates with barium, which is represented in total dissolved solids (TDS). It will therefore track TDS fairly closely. Conclusion: companies will be testing the very first flowback water to emerge from a fracked well. It will be Day 1, Minute 1 test results. 2.) There are two pits on a frack pad, one for "emergency" flowback and another, smaller one for drill cuttings and drilling mud. It is a basic principle in horizontal fracking to steer the drill bit through the horizontal strata with the highest gamma radiation readings (GAPI logs). The reason is that radioactivity correlates highly with total organic content (TOC) in the rock, and TOC correlates highly with oil and gas yields. This means that rock cuttings in the smaller drill mud and cuttings frack pit will often be more radioactive than flowback water. The IDNR knows this; yet it does not call for testing of drill bit pits as allowed under the Powers and duties section of the Act (§1- 15). 3.) The term "adjacent to" requires a "precise, clear standard" [IAPA, §100/5-20]. None is given. Does "adjacent to" mean 6 inches, 16 inches, 6 feet, 16 feet, or 60 feet? The IDNR does not say. 4.) Frack pad pipes and equipment can become incredibly radioactive over time. The very large temperature and pressure drops, as fluids move to the surface from thousands of feet underground, means that aqueous radioactive salts precipitate out as scale on pipes and equipment. The levels of radioactivity in pipe scale can exceed 100,000 picoCuries per gram and constitute a hazard to workers, or others who are exposed to recycled scrap metal from gas and oil operations. Yet, IDNR does not call on its General Assembly deferred "Power and authority" [Act, §1-15(e)] to test pipe, tanks, sludge, and equipment. This issue has been an issue in the oil and gas industry since the 1980s. Consequences: According to studies by the Illinois State Geological Survey, the Illinois New Albany Shale Formation, the source rock for our oil and gas reserves, has above average levels of uranium (29 ppm). Uranium decays into radium and thence radon. Both uranium and radium are water soluble. As noted, the U.S. Geological Survey has found oil field brine or produced water in Southern Illinois to have Radium226 levels that average more than 1,000 picoCuries / liter (USGS 1999). That reading is 67 times above the maximum contamination level of the EPA. Radium226 has a half life of 1,600 years. Uranium228 has a half life of 4.468 billion years. If these water soluble salts leach into our aquifers, nearby communities will require--if possible--very expensive water treatment for the next 1,000 years. We may have to return to rainwater harvesting with the modern equivalent of cisterns. The radioactive levels for produced water from shale gas operations are likely to be 2 to 4 times higher than oilfield brine -- on average, 2,000 to 4,000 picoCuries per liter. In addition, radon levels in methane, propane, and ethane can be dangerously high. When it becomes commercial to extract shale gas from the SE corner of the state, major markets, such as Springfield and Chicago, will only be 0.9 and 1.4 days removed from shale gas wellheads. Even though radon222 has a half life of only 3.8 days, the closeness of major Illinois retail gas markets will mean that large number of people will be breathing in high levels of radon when they cook meals. The average level of indoor exposure to radon in Illinois is already 4.4

## Fair Economy Illinois

---

pCi/L ( American Lung Association 2013). The EPA maximum level--the point at which corrective action should be taken--is 4.0 pCi/L, and the preferred level is =3.0 pCi/L. The turn to shale gas, with its high levels of radon, will also turn a major Illinois public health problem in the wrong direction. Radioactive scale in pipe and equipment presents another problem; high levels of radioactivity have been found in school playground equipment and bleachers in school sports stadiums in Mississippi and Texas. Do we want untested oil and gas field scrap metal sold into Illinois markets? Do we want our children exposed on a daily basis to radioactive metal? The present rules creates no barriers to such an outcome. The problems cited above are why Illinois, with its large number of nuclear power plants, has a Low-Level Radioactive Waste Management Act. It and OSHA are the applicable State and Federal agencies with respect to the issue of radioactive waste and work safety standards in settings with exposure to radioactivity. If we faithfully follow applicable State and federal laws, Illinois can minimize the pernicious problems other states are going to face from the uncontrolled release of radioactive elements into their water and soil and work and non-work settings. We should prevent these problem from the start. Cleanup, after the oil and gas industry is gone, will be dreadfully expensive.. Recommendations: 1. Define the test date as = Day 21, the point at which increases in test results begin to level off. 2. Test for "radioactivity" in (1) flowback/produced water, (2) drill cuttings, soil "adjacent to" (3) storage tanks and (4) reserve pits, and (5) pipes and well pad equipment. 3. Define "adjacent to" as between 6 and 12 inches with test samples to be taken within the top 6 inches of soil 4. The rules should also require that the requirements of the Illinois Low Level Radioactivity Waste Management Act be followed.

Sincerely, Girwana Baker Chicago, IL 60605

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Act §1-75(a)7 requires radioactivity testing "once per well site" for (1) flowback water and ground "adjacent to" (2) storage tanks and (3) reserve pits. Act § 1-120 requires IDNR compliance with all "applicable federal, State, and local laws." One applicable State law is the Illinois Low-Level Radioactive Waste Management Act (PA 83-991 / 420ILCS20). Another is the Occupational Health and Safety Administration (OSHA) standards for workplace safety in settings with exposure to radioactivity (29 CFR 1910.1096). Rules §245.850(d)1-E and §245.850(e) are incomplete and deficient, and these inadequacies can "constitute a serious threat"--indeed, deadly threat-- "to the public interest, safety, or welfare" of Illinois citizens." Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Notably absent from these proposed rules is a requirement for the testing of "produced water", the fluid that returns from the well during the later stage of production (after flowback). Under the proposed rules, "produced water" can be stored on site and/or can be "recycled", yet there is no testing requirement. Naturally occurring radioactive material (NORM) is found in "produced water" also. See Technologically enhanced naturally occurring radioactive materials in the oil industry (TENORM), Nukleonika 2009; 54(1):3-9, and sources cited therein, especially for TENORM in produced water in the U.S., available at [http://www.nukleonika.pl/www/back/full/vol54\\_2009/v54n1p003f.pdf](http://www.nukleonika.pl/www/back/full/vol54_2009/v54n1p003f.pdf). See also NORM is also found on scale in oil pipes and on fracking equipment. (See Kentucky Resources Council Proposes Comprehensive Plan For Investigating Radiological Contamination In Martha Oil Field. August 11, 2005. <http://www.kyrc.org/webnewspro/112381723236086.shtml>.) IDNR's definitions of "flowback water" and "produced water" are different. The two are distinguishably different enough that they are treated as separate types of fluid by both the Hydraulic Fracturing Regulatory Act and by the DNR Rules. Discharge of produced water onto the ground or into surface water or water drainage way is prohibited but it is not tested for radioactivity. This despite the fact that this fluid will be in contact with the naturally occurring radioactive elements in the ground for a longer period than the flowback and that it is much more likely to be radioactive. Problems: Failure to test produced water for radioactivity is problematic for a variety of reasons including: The health and safety of workers on the site who will be unaware of the levels of radioactivity they are being exposed to. The health and safety of workers transporting produced water who will also be in the dark regarding the levels of radioactivity they will be exposed to. The risk of storing radioactive material in tanks not created for storing radioactive materials. The risk of "recycling" produced water—radioactivity cannot be removed by recycling. The risk to the public in transporting radioactive materials Argonne National Laboratory recently cautioned about radiological doses: "It is commonly accepted that efforts should be undertaken at all times to keep radiological doses 'as low as reasonably achievable,' which is referred to as the ALARA principle or requirement." Overview of Radiological Dose and Risk Assessment (April 2011). DNR is failing to even adequately test for radioactivity and therefore, will not know the levels of radioactivity. How, then, can

## Fair Economy Illinois

---

DNR adequately protect workers and the general public? Elaboration: IDNR does not define a Fixed Date ( $\pm X$  days) for testing. Day 1, <Hour 1 test results will be orders of magnitude lower than either Day 2 or Day 10 tests results, and Day 10 tests results will be significantly lower than Day 80 ( $\pm 7$  days) results. Failure to specify a Fixed Test Date ( $\pm X$  days) renders test data so many irrelevant apples and oranges and allows companies to report suppressed, meaningless results by reporting Day 1, < 1 Hour data. The figure below, provided by the USGS, illustrates the nature of the problem. Please note that radium is not tested at Day 1, < 1 Hour. However, radium coprecipitates with barium, which is represented in total dissolved solids (TDS). It will therefore track TDS fairly closely. Conclusion: companies will be testing the very first flowback water to emerge from a fracked well. It will be Day 1, Minute 1 test results. 2.) DNR adequately protect workers and the general public? Elaboration: IDNR does not define a Fixed Date ( $\pm X$  days) for testing. Day 1, <Hour 1 test results will be orders of magnitude lower than either Day 2 or Day 10 tests results, and Day 10 tests results will be significantly lower than Day 80 ( $\pm 7$  days) results. Failure to specify a Fixed Test Date ( $\pm X$  days) renders test data so many irrelevant apples and oranges and allows companies to report suppressed, meaningless results by reporting Day 1, < 1 Hour data. The figure below, provided by the USGS, illustrates the nature of the problem. Please note that radium is not tested at Day 1, < 1 Hour. However, radium coprecipitates with barium, which is represented in total dissolved solids (TDS). It will therefore track TDS fairly closely. Conclusion: companies will be testing the very first flowback water to emerge from a fracked well. It will be Day 1, Minute 1 test results. 2.) There are two pits on a frack pad, one for "emergency" flowback and another, smaller one for drill cuttings and drilling mud. It is a basic principle in horizontal fracking to steer the drill bit through the horizontal strata with the highest gamma radiation readings (GAPI logs). The reason is that radioactivity correlates highly with total organic content (TOC) in the rock, and TOC correlates highly with oil and gas yields. This means that rock cuttings in the smaller drill mud and cuttings frack pit will often be more radioactive than flowback water. The IDNR knows this; yet it does not call for testing of drill bit pits as allowed under the Powers and duties section of the Act (§1- 15). 3.) The term "adjacent to" requires a "precise, clear standard" [IAPA, §100/5-20]. None is given. Does "adjacent to" mean 6 inches, 16 inches, 6 feet, 16 feet, or 60 feet? The IDNR does not say. 4.) Frack pad pipes and equipment can become incredibly radioactive over time. The very large temperature and pressure drops, as fluids move to the surface from thousands of feet underground, means that aqueous radioactive salts precipitate out as scale on pipes and equipment. The levels of radioactivity in pipe scale can exceed 100,000 picoCuries per gram and constitute a hazard to workers, or others who are exposed to recycled scrap metal from gas and oil operations. Yet, IDNR does not call on its General Assembly deferred "Power and authority" [Act, §1-15(e)] to test pipe, tanks, sludge, and equipment. This issue has been an issue in the oil and gas industry since the 1980s. Consequences: According to studies by the Illinois State Geological Survey, the Illinois New Albany Shale Formation, the source rock for our oil and gas reserves, has above average levels of uranium (29 ppm). Uranium decays into radium and thence radon. Both uranium and radium are water soluble. As noted, the U.S. Geological Survey has found oil field brine or produced water in Southern Illinois to have Radium226 levels that average more than 1,000 picoCuries / liter (USGS 1999). That reading is 67 times above the maximum contamination level of the EPA. Radium226 has a half life of 1,600 years. Uranium228 has a half life of 4.468 billion years. If these water soluble salts leach into our aquifers, nearby communities will require--if possible--very expensive water treatment for the next 1,000 years. We may have to return to rainwater harvesting with the modern equivalent of cisterns. The radioactive levels for produced water from shale gas operations are likely to be 2 to 4 times higher than oilfield brine -- on average, 2,000 to 4,000 picoCuries per liter. In addition, radon levels in methane, propane, and ethane can be dangerously high. When it becomes commercial to extract shale gas from the SE corner of the state, major markets, such as Springfield and Chicago, will only be 0.9 and 1.4 days removed from shale gas wellheads. Even though radon222 has a half life of only 3.8 days, the closeness of major Illinois retail gas markets will mean that large number of people will be breathing in high levels of radon when they cook meals. The average level of indoor exposure to radon in Illinois is already 4.4

## Fair Economy Illinois

---

pCi/L ( American Lung Association 2013). The EPA maximum level--the point at which corrective action should be taken--is 4.0 pCi/L, and the preferred level is =3.0 pCi/L. The turn to shale gas, with its high levels of radon, will also turn a major Illinois public health problem in the wrong direction. Radioactive scale in pipe and equipment presents another problem; high levels of radioactivity have been found in school playground equipment and bleachers in school sports stadiums in Mississippi and Texas. Do we want untested oil and gas field scrap metal sold into Illinois markets? Do we want our children exposed on a daily basis to radioactive metal? The present rules creates no barriers to such an outcome. The problems cited above are why Illinois, with its large number of nuclear power plants, has a Low-Level Radioactive Waste Management Act. It and OSHA are the applicable State and Federal agencies with respect to the issue of radioactive waste and work safety standards in settings with exposure to radioactivity. If we faithfully follow applicable State and federal laws, Illinois can minimize the pernicious problems other states are going to face from the uncontrolled release of radioactive elements into their water and soil and work and non-work settings. We should prevent these problem from the start. Cleanup, after the oil and gas industry is gone, will be dreadfully expensive.. Recommendations: 1. Define the test date as = Day 21, the point at which increases in test results begin to level off. 2. Test for "radioactivity" in (1) flowback/produced water, (2) drill cuttings, soil "adjacent to" (3) storage tanks and (4) reserve pits, and (5) pipes and well pad equipment. 3. Define "adjacent to" as between 6 and 12 inches with test samples to be taken within the top 6 inches of soil 4. The rules should also require that the requirements of the Illinois Low Level Radioactivity Waste Management Act be followed.

Sincerely, Gus Novoa Chicago, IL 60637

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Act §1-75(a)7 requires radioactivity testing "once per well site" for (1) flowback water and ground "adjacent to" (2) storage tanks and (3) reserve pits. Act § 1-120 requires IDNR compliance with all "applicable federal, State, and local laws." One applicable State law is the Illinois Low-Level Radioactive Waste Management Act (PA 83-991 / 420ILCS20). Another is the Occupational Health and Safety Administration (OSHA) standards for workplace safety in settings with exposure to radioactivity (29 CFR 1910.1096). Rules §245.850(d)1-E and §245.850(e) are incomplete and deficient, and these inadequacies can "constitute a serious threat"--indeed, deadly threat-- "to the public interest, safety, or welfare" of Illinois citizens." Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Notably absent from these proposed rules is a requirement for the testing of "produced water", the fluid that returns from the well during the later stage of production (after flowback). Under the proposed rules, "produced water" can be stored on site and/or can be "recycled", yet there is no testing requirement. Naturally occurring radioactive material (NORM) is found in "produced water" also. See Technologically enhanced naturally occurring radioactive materials in the oil industry (TENORM), Nukleonika 2009; 54(1):3-9, and sources cited therein, especially for TENORM in produced water in the U.S., available at [http://www.nukleonika.pl/www/back/full/vol54\\_2009/v54n1p003f.pdf](http://www.nukleonika.pl/www/back/full/vol54_2009/v54n1p003f.pdf). See also NORM is also found on scale in oil pipes and on fracking equipment. (See Kentucky Resources Council Proposes Comprehensive Plan For Investigating Radiological Contamination In Martha Oil Field. August 11, 2005. <http://www.kyrc.org/webnewspro/112381723236086.shtml>.) IDNR's definitions of "flowback water" and "produced water" are different. The two are distinguishably different enough that they are treated as separate types of fluid by both the Hydraulic Fracturing Regulatory Act and by the DNR Rules. Discharge of produced water onto the ground or into surface water or water drainage way is prohibited but it is not tested for radioactivity. This despite the fact that this fluid will be in contact with the naturally occurring radioactive elements in the ground for a longer period than the flowback and that it is much more likely to be radioactive. Problems: Failure to test produced water for radioactivity is problematic for a variety of reasons including: The health and safety of workers on the site who will be unaware of the levels of radioactivity they are being exposed to. The health and safety of workers transporting produced water who will also be in the dark regarding the levels of radioactivity they will be exposed to. The risk of storing radioactive material in tanks not created for storing radioactive materials. The risk of "recycling" produced water—radioactivity cannot be removed by recycling. The risk to the public in transporting radioactive materials Argonne National Laboratory recently cautioned about radiological doses: "It is commonly accepted that efforts should be undertaken at all times to keep radiological doses 'as low as reasonably achievable,' which is referred to as the ALARA principle or requirement." Overview of Radiological Dose and Risk Assessment (April 2011). DNR is failing to even adequately test for radioactivity and therefore, will not know the levels of radioactivity. How, then, can

## Fair Economy Illinois

---

DNR adequately protect workers and the general public? Elaboration: IDNR does not define a Fixed Date ( $\pm X$  days) for testing. Day 1, <Hour 1 test results will be orders of magnitude lower than either Day 2 or Day 10 tests results, and Day 10 tests results will be significantly lower than Day 80 ( $\pm 7$  days) results. Failure to specify a Fixed Test Date ( $\pm X$  days) renders test data so many irrelevant apples and oranges and allows companies to report suppressed, meaningless results by reporting Day 1, < 1 Hour data. The figure below, provided by the USGS, illustrates the nature of the problem. Please note that radium is not tested at Day 1, < 1 Hour. However, radium coprecipitates with barium, which is represented in total dissolved solids (TDS). It will therefore track TDS fairly closely. Conclusion: companies will be testing the very first flowback water to emerge from a fracked well. It will be Day 1, Minute 1 test results. 2.) There are two pits on a frack pad, one for "emergency" flowback and another, smaller one for drill cuttings and drilling mud. It is a basic principle in horizontal fracking to steer the drill bit through the horizontal strata with the highest gamma radiation readings (GAPI logs). The reason is that radioactivity correlates highly with total organic content (TOC) in the rock, and TOC correlates highly with oil and gas yields. This means that rock cuttings in the smaller drill mud and cuttings frack pit will often be more radioactive than flowback water. The IDNR knows this; yet it does not call for testing of drill bit pits as allowed under the Powers and duties section of the Act (§1- 15). 3.) The term "adjacent to" requires a "precise, clear standard" [IAPA, §100/5-20]. None is given. Does "adjacent to" mean 6 inches, 16 inches, 6 feet, 16 feet, or 60 feet? The IDNR does not say. 4.) Frack pad pipes and equipment can become incredibly radioactive over time. The very large temperature and pressure drops, as fluids move to the surface from thousands of feet underground, means that aqueous radioactive salts precipitate out as scale on pipes and equipment. The levels of radioactivity in pipe scale can exceed 100,000 picoCuries per gram and constitute a hazard to workers, or others who are exposed to recycled scrap metal from gas and oil operations. Yet, IDNR does not call on its General Assembly deferred "Power and authority" [Act, §1-15(e)] to test pipe, tanks, sludge, and equipment. This issue has been an issue in the oil and gas industry since the 1980s. Consequences: According to studies by the Illinois State Geological Survey, the Illinois New Albany Shale Formation, the source rock for our oil and gas reserves, has above average levels of uranium (29 ppm). Uranium decays into radium and thence radon. Both uranium and radium are water soluble. As noted, the U.S. Geological Survey has found oil field brine or produced water in Southern Illinois to have Radium226 levels that average more than 1,000 picoCuries / liter (USGS 1999). That reading is 67 times above the maximum contamination level of the EPA. Radium226 has a half life of 1,600 years. Uranium228 has a half life of 4.468 billion years. If these water soluble salts leach into our aquifers, nearby communities will require--if possible--very expensive water treatment for the next 1,000 years. We may have to return to rainwater harvesting with the modern equivalent of cisterns. The radioactive levels for produced water from shale gas operations are likely to be 2 to 4 times higher than oilfield brine -- on average, 2,000 to 4,000 picoCuries per liter. In addition, radon levels in methane, propane, and ethane can be dangerously high. When it becomes commercial to extract shale gas from the SE corner of the state, major markets, such as Springfield and Chicago, will only be 0.9 and 1.4 days removed from shale gas wellheads. In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Act §1-75(a)7 requires radioactivity testing "once per well site" for (1) flowback water and ground "adjacent to" (2) storage tanks and (3) reserve pits. Act § 1-120 requires IDNR compliance with all "applicable federal, State, and local laws." One applicable State law is the Illinois Low-Level Radioactive Waste Management Act (PA 83-991 / 420ILCS20). Another is the Occupational Health and Safety Administration (OSHA) standards for workplace safety in settings with exposure to radioactivity (29 CFR 1910.1096). Rules §245.850(d)1-E and §245.850(e) are incomplete and deficient, and these inadequacies can "constitute a serious threat"--indeed, deadly threat-- "to the public interest, safety, or welfare" of Illinois citizens." Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Notably absent from these proposed rules is a requirement for the testing of "produced water", the fluid that returns from the well during the later stage of production (after flowback). Under the proposed rules, "produced water" can be stored on site and/or can be "recycled", yet there is no testing requirement. Naturally occurring radioactive material (NORM) is found in "produced water" also. See Technologically enhanced naturally occurring radioactive materials in the oil industry (TENORM), Nukleonika 2009; 54(1):3-9, and sources cited therein, especially for TENORM in produced water in the U.S., available at [http://www.nukleonika.pl/www/back/full/vol54\\_2009/v54n1p003f.pdf](http://www.nukleonika.pl/www/back/full/vol54_2009/v54n1p003f.pdf). See also NORM is also found on scale in oil pipes and on fracking equipment. (See Kentucky Resources Council Proposes Comprehensive Plan For Investigating Radiological Contamination In Martha Oil Field. August 11, 2005. <http://www.kyrc.org/webnewspro/112381723236086.shtml>.) IDNR's definitions of "flowback water" and "produced water" are different. The two are distinguishably different enough that they are treated as separate types of fluid by both the Hydraulic Fracturing Regulatory Act and by the DNR Rules. Discharge of produced water onto the ground or into surface water or water drainage way is prohibited but it is not tested for radioactivity. This despite the fact that this fluid will be in contact with the naturally occurring radioactive elements in the ground for a longer period than the flowback and that it is much more likely to be radioactive. Problems: Failure to test produced water for radioactivity is problematic for a variety of reasons including: The health and safety of workers on the site who will be unaware of the levels of radioactivity they are being exposed to. The health and safety of workers transporting produced water who will also be in the dark regarding the levels of radioactivity they will be exposed to. The risk of storing radioactive material in tanks not created for storing radioactive materials. The risk of "recycling" produced water—radioactivity cannot be removed by recycling. The risk to the public in transporting radioactive materials Argonne National Laboratory recently cautioned about radiological doses: "It is commonly accepted that efforts should be undertaken at all times to keep radiological doses 'as low as reasonably achievable,' which is referred to as the ALARA principle or requirement." Overview of Radiological Dose and Risk Assessment (April 2011). DNR is failing to even adequately test for radioactivity and therefore, will not know the levels of radioactivity. How, then, can

## Fair Economy Illinois

DNR adequately protect workers and the general public? Elaboration: IDNR does not define a Fixed Date ( $\pm X$  days) for testing. Day 1, <Hour 1 test results will be orders of magnitude lower than either Day 2 or Day 10 tests results, and Day 10 tests results will be significantly lower than Day 80 ( $\pm 7$  days) results. Failure to specify a Fixed Test Date ( $\pm X$  days) renders test data so many irrelevant apples and oranges and allows companies to report suppressed, meaningless results by reporting Day 1, < 1 Hour data. The figure below, provided by the USGS, illustrates the nature of the problem. Please note that radium is not tested at Day 1, < 1 Hour. However, radium coprecipitates with barium, which is represented in total dissolved solids (TDS). It will therefore track TDS fairly closely. Conclusion: companies will be testing the very first flowback water to emerge from a fracked well. It will be Day 1, Minute 1 test results. 2.) There are two pits on a frack pad, one for "emergency" flowback and another, smaller one for drill cuttings and drilling mud. It is a basic principle in horizontal fracking to steer the drill bit through the horizontal strata with the highest gamma radiation readings (GAPI logs). The reason is that radioactivity correlates highly with total organic content (TOC) in the rock, and TOC correlates highly with oil and gas yields. This means that rock cuttings in the smaller drill mud and cuttings frack pit will often be more radioactive than flowback water. The IDNR knows this; yet it does not call for testing of drill bit pits as allowed under the Powers and duties section of the Act (§1- 15). 3.) The term "adjacent to" requires a "precise, clear standard" [IAPA, §100/5-20]. None is given. Does "adjacent to" mean 6 inches, 16 inches, 6 feet, 16 feet, or 60 feet? The IDNR does not say. 4.) Frack pad pipes and equipment can become incredibly radioactive over time. The very large temperature and pressure drops, as fluids move to the surface from thousands of feet underground, means that aqueous radioactive salts precipitate out as scale on pipes and equipment. The levels of radioactivity in pipe scale can exceed 100,000 picoCuries per gram and constitute a hazard to workers, or others who are exposed to recycled scrap metal from gas and oil operations. Yet, IDNR does not call on its General Assembly deferred "Power and authority" [Act, §1-15(e)] to test pipe, tanks, sludge, and equipment. This issue has been an issue in the oil and gas industry since the 1980s. Consequences: According to studies by the Illinois State Geological Survey, the Illinois New Albany Shale Formation, the source rock for our oil and gas reserves, has above average levels of uranium (29 ppm). Uranium decays into radium and thence radon. Both uranium and radium are water soluble. As noted, the U.S. Geological Survey has found oil field brine or produced water in Southern Illinois to have Radium226 levels that average more than 1,000 picoCuries / liter (USGS 1999). That reading is 67 times above the maximum contamination level of the EPA. Radium226 has a half life of 1,600 years. Uranium228 has a half life of 4.468 billion years. If these water soluble salts leach into our aquifers, nearby communities will require--if possible--very expensive water treatment for the next 1,000 years. We may have to return to rainwater harvesting with the modern equivalent of cisterns. The radioactive levels for produced water from shale gas operations are likely to be 2 to 4 times higher than oilfield brine -- on average, 2,000 to 4,000 picoCuries per liter. In addition, radon levels in methane, propane, and ethane can be dangerously high. When it becomes commercial to extract shale gas from the SE corner of the state, major markets, such as Springfield and Chicago, will only be 0.9 and 1.4 days removed from shale gas wellheads. Even though radon222 has a half life of only 3.8 days, the closeness of major Illinois retail gas markets will mean that large number of people will be breathing in high levels of radon when they cook meals. The average level of indoor exposure to radon in Illinois is already 4.4

## Fair Economy Illinois

---

pCi/L ( American Lung Association 2013). The EPA maximum level--the point at which corrective action should be taken--is 4.0 pCi/L, and the preferred level is =3.0 pCi/L. The turn to shale gas, with its high levels of radon, will also turn a major Illinois public health problem in the wrong direction. Radioactive scale in pipe and equipment presents another problem; high levels of radioactivity have been found in school playground equipment and bleachers in school sports stadiums in Mississippi and Texas. Do we want untested oil and gas field scrap metal sold into Illinois markets? Do we want our children exposed on a daily basis to radioactive metal? The present rules creates no barriers to such an outcome. The problems cited above are why Illinois, with its large number of nuclear power plants, has a Low-Level Radioactive Waste Management Act. It and OSHA are the applicable State and Federal agencies with respect to the issue of radioactive waste and work safety standards in settings with exposure to radioactivity. If we faithfully follow applicable State and federal laws, Illinois can minimize the pernicious problems other states are going to face from the uncontrolled release of radioactive elements into their water and soil and work and non-work settings. We should prevent these problem from the start. Cleanup, after the oil and gas industry is gone, will be dreadfully expensive.. Recommendations: 1. Define the test date as = Day 21, the point at which increases in test results begin to level off. 2. Test for "radioactivity" in (1) flowback/produced water, (2) drill cuttings, soil "adjacent to" (3) storage tanks and (4) reserve pits, and (5) pipes and well pad equipment. 3. Define "adjacent to" as between 6 and 12 inches with test samples to be taken within the top 6 inches of soil 4. The rules should also require that the requirements of the Illinois Low Level Radioactivity Waste Management Act be followed.

Sincerely, James Alstrum Normal, IL 61761
