Section 1-75 of the Hydraulic Fracturing Regulator Act mandates that “excess hydraulic fracturing flowback captured for temporary storage in a reserve pit as provided in paragraph (2) of this subsection must be removed from the well site within 7 days.” But Section 245.850 of the proposed rules states, “Any excess hydraulic fracturing flowback captured for temporary storage in a reserve pit as provided in Section 245.825 must be removed from the well site or transferred to storage in above-ground tanks for later disposal or recycling within 7 days after completion of high volume horizontal hydraulic fracturing operations.” Problem: The amendment of “after completion of high volume horizontal hydraulic fracturing operations” opens the door for the potential abuse of emergency pits. Storage in closed tanks can be costly for the industry. An unscrupulous operator wanting to cut costs could simply claim that there was more flowback than expected and end up using open pits for storage for the duration of the fracking process. The clear intent of the statute is to ensure that wastewater is stored in tanks except in the emergency event of an unforeseeable overflow, in which case it is preferable that the overflow go to a pit than simply spill on the ground. But in such event, the overflow is expressly required in the statute to be removed within a week. Through omission and misinterpretation, the regulations are not implementing this statutory directive. Section 245.210(a)(11), requires that an applicant submit a Hydraulic Fracturing Fluids and Flowback Plan. The plan does not include requirements to ensure that tank capacity is accurately calculated. Without such method, there is nothing in the regulations to prevent operators from underestimating the size of the tanks they need, so as to make routine use of the reserve pit for the resulting overflows. Operators presumably have an economic incentive to do so in order to hold down the cost of tank storage. Compounding this incentive is the Department’s weakening of the statutory directive that fluids deposited in a reserve pit be removed within 7 days (Section 1-75(c)(5)). The regulations fail to require such prompt removal, allowing, at subsection 245.850(c), the overflow to remain in the reserve pits until 7 days “after completion of high volume horizontal hydraulic fracturing operations.” Certainly on a multi-well pad, hydraulic fracturing operations can continue for a month or more, meaning that the flowback fluid could be left sitting in the reserve pit, creating environmental risk, for much longer than a week. Revisions needed: First, require that drillers anticipate appropriate sized tanks for sufficient storage of flowback and produced water by establishing a method for tank capacity calculation. Second, clarify that wastewater must be removed from the pit within 7 days of the event that triggered the use of the pit rather than 7 days after fracking operations are complete, in accordance with the law.

Sincerely, M J Smerken Murphysboro, IL 62966

The plan does not include requirements to ensure that tank capacity is accurately calculated. Without such method, there is nothing in the regulations to prevent operators from underestimating the size of the tanks they need, so as to make routine use of the reserve pit for the resulting overflows. Operators presumably have an economic incentive to do so in order to hold down the cost of tank storage. Compounding this incentive is the Department’s weakening of the statutory directive that fluids deposited in a reserve pit be removed within 7 days (Section 1-75(c)(5)). The regulations fail to require such prompt removal, allowing, at subsection 245.850(c), the overflow to remain in the reserve pits until 7 days “after completion of high volume horizontal hydraulic fracturing operations.” Certainly on a multi-well pad, hydraulic fracturing operations can continue for a month or more, meaning that the flowback fluid could be left sitting in the reserve pit, creating environmental risk, for much longer than a week. Revisions needed: First, require that drillers anticipate appropriate sized tanks for sufficient storage of flowback and produced water by establishing a method for tank capacity calculation. Second, clarify that wastewater must be removed from the pit within 7 days of the event that triggered the use of the pit rather than 7 days after fracking operations are complete, in accordance with the law.

Sincerely, Min Li Naperville, IL 60564

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Section 1-75 of the Hydraulic Fracturing Regulator Act mandates that “excess hydraulic fracturing flowback captured for temporary storage in a reserve pit as provided in paragraph (2) of this subsection must be removed from the well site within 7 days.” But Section 245.850 of the proposed rules states, “Any excess hydraulic fracturing flowback captured for temporary storage in a reserve pit as provided in Section 245.825 must be removed from the well site or transferred to storage in above-ground tanks for later disposal or recycling within 7 days after completion of high volume horizontal hydraulic fracturing operations.” Problem: The amendment of “after completion of high volume horizontal hydraulic fracturing operations” opens the door for the potential abuse of emergency pits. Storage in closed tanks can be costly for the industry. An unscrupulous operator wanting to cut costs could simply claim that there was more flowback than expected and end up using open pits for storage for the duration of the fracking process. The clear intent of the statute is to ensure that wastewater is stored in tanks except in the emergency event of an unforeseeable overflow, in which case it is preferable that the overflow go to a pit than simply spill on the ground. But in such event, the overflow is expressly required in the statute to be removed within a week. Through omission and misinterpretation, the regulations are not implementing this statutory directive. Section 245.210(a)(11), requires that an applicant submit a Hydraulic Fracturing Fluids and Flowback Plan. The plan does not include requirements to ensure that tank capacity is accurately calculated. Without such method, there is nothing in the regulations to prevent operators from underestimating the size of the tanks they need, so as to make routine use of the reserve pit for the resulting overflows. Operators presumably have an economic incentive to do so in order to hold down the cost of tank storage. Compounding this incentive is the Department’s weakening of the statutory directive that fluids deposited in a reserve pit be removed within 7 days (Section 1-75(c)(5)). The regulations fail to require such prompt removal, allowing, at subsection 245.850(c), the overflow to remain in the reserve pits until 7 days “after completion of high volume horizontal hydraulic fracturing operations.” Certainly on a multi-well pad, hydraulic fracturing operations can continue for a month or more, meaning that the flowback fluid could be left sitting in the reserve pit, creating environmental risk, for much longer than a week. The clear intent of the statute is to ensure that wastewater is stored in tanks except in the emergency event of an unforeseeable overflow, in which case it is preferable that the overflow go to a pit than simply spill on the ground. But in such event, the overflow is expressly required in the statute to be removed within a week. Through omission and misinterpretation, the regulations are not implementing this statutory directive. Section 245.210(a)(11), requires that an applicant submit a Hydraulic Fracturing Fluids and Flowback Plan. The plan does not include requirements to ensure that tank capacity is accurately calculated. Without such method, there is nothing in the regulations to prevent operators from underestimating the size of the tanks they need, so as to make routine use of the reserve pit for the resulting overflows. Operators presumably have an economic incentive to do so in order to hold down the cost of tank storage. Compounding this incentive is the Department’s weakening of the statutory directive that fluids deposited in a reserve pit be removed within 7 days (Section 1-75(c)(5)). The regulations fail to require such prompt removal, allowing, at subsection 245.850(c), the overflow to remain in the reserve pits until 7 days “after completion of high volume horizontal hydraulic fracturing operations.” Certainly on a multi-well pad, hydraulic fracturing operations can continue for a month or more, meaning that the flowback fluid could be left sitting in the reserve pit, creating environmental risk, for much longer than a week. Revisions needed: First, require that drillers anticipate appropriate sized tanks for sufficient storage of flowback and produced water by establishing a method for tank capacity calculation. Second, clarify that wastewater must be removed from the pit within 7 days of the event that triggered the use of the pit rather than 7 days after fracking operations are complete, in accordance with the law.

Sincerely, Norma Claire Moruzzi Chicago, IL 60640

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Section 1-75 of the Hydraulic Fracturing Regulator Act mandates that “excess hydraulic fracturing flowback captured for temporary storage in a reserve pit as provided in paragraph (2) of this subsection must be removed from the well site within 7 days.” But Section 245.850 of the proposed rules states, “Any excess hydraulic fracturing flowback captured for temporary storage in a reserve pit as provided in Section 245.825 must be removed from the well site or transferred to storage in above-ground tanks for later disposal or recycling within 7 days after completion of high volume horizontal hydraulic fracturing operations.” Problem: The amendment of “after completion of high volume horizontal hydraulic fracturing operations” opens the door for the potential abuse of emergency pits. Storage in closed tanks can be costly for the industry. An unscrupulous operator wanting to cut costs could simply claim that there was more flowback than expected and end up using open pits for storage for the duration of the fracking process. The clear intent of the statute is to ensure that wastewater is stored in tanks except in the emergency event of an unforeseeable overflow, in which case it is preferable that the overflow go to a pit than simply spill on the ground. But in such event, the overflow is expressly required in the statute to be removed within a week. Through omission and misinterpretation, the regulations are not implementing this statutory directive. Section 245.210(a)(11), requires that an applicant submit a Hydraulic Fracturing Fluids and Flowback Plan. In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Section 1-75 of the Hydraulic Fracturing Regulator Act mandates that “excess hydraulic fracturing flowback captured for temporary storage in a reserve pit as provided in paragraph (2) of this subsection must be removed from the well site within 7 days.” But Section 245.850 of the proposed rules states, “Any excess hydraulic fracturing flowback captured for temporary storage in a reserve pit as provided in Section 245.825 must be removed from the well site or transferred to storage in above-ground tanks for later disposal or recycling within 7 days after completion of high volume horizontal hydraulic fracturing operations.” Problem: The amendment of “after completion of high volume horizontal hydraulic fracturing operations” opens the door for the potential abuse of emergency pits. Storage in closed tanks can be costly for the industry. An unscrupulous operator wanting to cut costs could simply claim that there was more flowback than expected and end up using open pits for storage for the duration of the fracking process. The clear intent of the statute is to ensure that wastewater is stored in tanks except in the emergency event of an unforeseeable overflow, in which case it is preferable that the overflow go to a pit than simply spill on the ground. But in such event, the overflow is expressly required in the statute to be removed within a week. Through omission and misinterpretation, the regulations are not implementing this statutory directive. Section 245.210(a)(11), requires that an applicant submit a Hydraulic Fracturing Fluids and Flowback Plan. The plan does not include requirements to ensure that tank capacity is accurately calculated. Without such method, there is nothing in the regulations to prevent operators from underestimating the size of the tanks they need, so as to make routine use of the reserve pit for the resulting overflows. Operators presumably have an economic incentive to do so in order to hold down the cost of tank storage. Compounding this incentive is the Department’s weakening of the statutory directive that fluids deposited in a reserve pit be removed within 7 days (Section 1-75(c)(5)). The regulations fail to require such prompt removal, allowing, at subsection 245.850(c), the overflow to remain in the reserve pits until 7 days “after completion of high volume horizontal hydraulic fracturing operations.” Certainly on a multi-well pad, hydraulic fracturing operations can continue for a month or more, meaning that the flowback fluid could be left sitting in the reserve pit, creating environmental risk, for much longer than a week. Revisions needed: First, require that drillers anticipate appropriate sized tanks for sufficient storage of flowback and produced water by establishing a method for tank capacity calculation. Second, clarify that wastewater must be removed from the pit within 7 days of the event that triggered the use of the pit rather than 7 days after fracking operations are complete, in accordance with the law.

Without such method, there is nothing in the regulations to prevent operators from underestimating the size of the tanks they need, so as to make routine use of the reserve pit for the resulting overflows. Operators presumably have an economic incentive to do so in order to hold down the cost of tank storage. Compounding this incentive is the Department’s weakening of the statutory directive that fluids deposited in a reserve pit be removed within 7 days (Section 1-75(c)(5)). The regulations fail to require such prompt removal, allowing, at subsection 245.850(c), the overflow to remain in the reserve pits until 7 days “after completion of high volume horizontal hydraulic fracturing operations.” Certainly on a multi-well pad, hydraulic fracturing operations can continue for a month or more, meaning that the flowback fluid could be left sitting in the reserve pit, creating environmental risk, for much longer than a week. Revisions needed: First, require that drillers anticipate appropriate sized tanks for sufficient storage of flowback and produced water by establishing a method for tank capacity calculation. Second, clarify that wastewater must be removed from the pit within 7 days of the event that triggered the use of the pit rather than 7 days after fracking operations are complete, in accordance with the law.

Sincerely, Rebecca McBride Mahomet, IL 61875

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Section 1-75 of the Hydraulic Fracturing Regulator Act mandates that “excess hydraulic fracturing flowback captured for temporary storage in a reserve pit as provided in paragraph (2) of this subsection must be removed from the well site within 7 days.” But Section 245.850 of the proposed rules states, “Any excess hydraulic fracturing flowback captured for temporary storage in a reserve pit as provided in Section 245.825 must be removed from the well site or transferred to storage in above-ground tanks for later disposal or recycling within 7 days after completion of high volume horizontal hydraulic fracturing operations.” Problem: The amendment of “after completion of high volume horizontal hydraulic fracturing operations” opens the door for the potential abuse of emergency pits. Storage in closed tanks can be costly for the industry. An unscrupulous operator wanting to cut costs could simply claim that there was more flowback than expected and end up using open pits for storage for the duration of the fracking process. The clear intent of the statute is to ensure that wastewater is stored in tanks except in the emergency event of an unforeseeable overflow, in which case it is preferable that the overflow go to a pit than simply spill on the ground. But in such event, the overflow is expressly required in the statute to be removed within a week. Through omission and misinterpretation, the regulations are not implementing this statutory directive. Section 245.210(a)(11), requires that an applicant submit a Hydraulic Fracturing Fluids and Flowback Plan. The plan does not include requirements to ensure that tank capacity is accurately calculated. Without such method, there is nothing in the regulations to prevent operators from underestimating the size of the tanks they need, so as to make routine use of the reserve pit for the resulting overflows. Operators presumably have an economic incentive to do so in order to hold down the cost of tank storage. Compounding this incentive is the Department’s weakening of the statutory directive that fluids deposited in a reserve pit be removed within 7 days (Section 1-75(c)(5)). The regulations fail to require such prompt removal, allowing, at subsection 245.850(c), the overflow to remain in the reserve pits until 7 days “after completion of high volume horizontal hydraulic fracturing operations.” Certainly on a multi-well pad, hydraulic fracturing operations can continue for a month or more, meaning that the flowback fluid could be left sitting in the reserve pit, creating environmental risk, for much longer than a week. An unscrupulous operator wanting to cut costs could simply claim that there was more flowback than expected and end up using open pits for storage for the duration of the fracking process. The clear intent of the statute is to ensure that wastewater is stored in tanks except in the emergency event of an unforeseeable overflow, in which case it is preferable that the overflow go to a pit than simply spill on the ground. But in such event, the overflow is expressly required in the statute to be removed within a week. Through omission and misinterpretation, the regulations are not implementing this statutory directive. Section 245.210(a)(11), requires that an applicant submit a Hydraulic Fracturing Fluids and Flowback Plan. The plan does not include requirements to ensure that tank capacity is accurately calculated. Without such method, there is nothing in the regulations to prevent operators from underestimating the size of the tanks they need, so as to make routine use of the reserve pit for the resulting overflows. Operators presumably have an economic incentive to do so in order to hold down the cost of tank storage. Compounding this incentive is the Department’s weakening of the statutory directive that fluids deposited in a reserve pit be removed within 7 days (Section 1-75(c)(5)). The regulations fail to require such prompt removal, allowing, at subsection 245.850(c), the overflow to remain in the reserve pits until 7 days “after completion of high volume horizontal hydraulic fracturing operations.” Certainly on a multi-well pad, hydraulic fracturing operations can continue for a month or more, meaning that the flowback fluid could be left sitting in the reserve pit, creating environmental risk, for much longer than a week. Revisions needed: First, require that drillers anticipate appropriate sized tanks for sufficient storage of flowback and produced water by establishing a method for tank capacity calculation. Second, clarify that wastewater must be removed from the pit within 7 days of the event that triggered the use of the pit rather than 7 days after fracking operations are complete, in accordance with the law.

Sincerely, Sandeep Malladi Chicago, IL 60637

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Section 1-75 of the Hydraulic Fracturing Regulator Act mandates that “excess hydraulic fracturing flowback captured for temporary storage in a reserve pit as provided in paragraph (2) of this subsection must be removed from the well site within 7 days.” But Section 245.850 of the proposed rules states, “Any excess hydraulic fracturing flowback captured for temporary storage in a reserve pit as provided in Section 245.825 must be removed from the well site or transferred to storage in above-ground tanks for later disposal or recycling within 7 days after completion of high volume horizontal hydraulic fracturing operations.” Problem: The amendment of “after completion of high volume horizontal hydraulic fracturing operations” opens the door for the potential abuse of emergency pits. Storage in closed tanks can be costly for the industry. An unscrupulous operator wanting to cut costs could simply claim that there was more flowback than expected and end up using open pits for storage for the duration of the fracking process. The clear intent of the statute is to ensure that wastewater is stored in tanks except in the emergency event of an unforeseeable overflow, in which case it is preferable that the overflow go to a pit than simply spill on the ground. But in such event, the overflow is expressly required in the statute to be removed within a week. In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Section 1-75 of the Hydraulic Fracturing Regulator Act mandates that “excess hydraulic fracturing flowback captured for temporary storage in a reserve pit as provided in paragraph (2) of this subsection must be removed from the well site within 7 days.” But Section 245.850 of the proposed rules states, “Any excess hydraulic fracturing flowback captured for temporary storage in a reserve pit as provided in Section 245.825 must be removed from the well site or transferred to storage in above-ground tanks for later disposal or recycling within 7 days after completion of high volume horizontal hydraulic fracturing operations.” Problem: The amendment of “after completion of high volume horizontal hydraulic fracturing operations” opens the door for the potential abuse of emergency pits. Storage in closed tanks can be costly for the industry. An unscrupulous operator wanting to cut costs could simply claim that there was more flowback than expected and end up using open pits for storage for the duration of the fracking process. The clear intent of the statute is to ensure that wastewater is stored in tanks except in the emergency event of an unforeseeable overflow, in which case it is preferable that the overflow go to a pit than simply spill on the ground. But in such event, the overflow is expressly required in the statute to be removed within a week. Through omission and misinterpretation, the regulations are not implementing this statutory directive. Section 245.210(a)(11), requires that an applicant submit a Hydraulic Fracturing Fluids and Flowback Plan. The plan does not include requirements to ensure that tank capacity is accurately calculated. Without such method, there is nothing in the regulations to prevent operators from underestimating the size of the tanks they need, so as to make routine use of the reserve pit for the resulting overflows. Operators presumably have an economic incentive to do so in order to hold down the cost of tank storage. Compounding this incentive is the Department’s weakening of the statutory directive that fluids deposited in a reserve pit be removed within 7 days (Section 1-75(c)(5)). The regulations fail to require such prompt removal, allowing, at subsection 245.850(c), the overflow to remain in the reserve pits until 7 days “after completion of high volume horizontal hydraulic fracturing operations.” Certainly on a multi-well pad, hydraulic fracturing operations can continue for a month or more, meaning that the flowback fluid could be left sitting in the reserve pit, creating environmental risk, for much longer than a week. Revisions needed: First, require that drillers anticipate appropriate sized tanks for sufficient storage of flowback and produced water by establishing a method for tank capacity calculation. Second, clarify that wastewater must be removed from the pit within 7 days of the event that triggered the use of the pit rather than 7 days after fracking operations are complete, in accordance with the law.

Sincerely, Simone Serhan Chicago, IL 60605

Operators presumably have an economic incentive to do so in order to hold down the cost of tank storage. Compounding this incentive is the Department’s weakening of the statutory directive that fluids deposited in a reserve pit be removed within 7 days (Section 1-75(c)(5)). The regulations fail to require such prompt removal, allowing, at subsection 245.850(c), the overflow to remain in the reserve pits until 7 days “after completion of high volume horizontal hydraulic fracturing operations.” Certainly on a multi-well pad, hydraulic fracturing operations can continue for a month or more, meaning that the flowback fluid could be left sitting in the reserve pit, creating environmental risk, for much longer than a week. Revisions needed: First, require that drillers anticipate appropriate sized tanks for sufficient storage of flowback and produced water by establishing a method for tank capacity calculation. Second, clarify that wastewater must be removed from the pit within 7 days of the event that triggered the use of the pit rather than 7 days after fracking operations are complete, in accordance with the law.

Sincerely, Vik Lobo Chicago, IL 60637

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Section 1-75 of the Hydraulic Fracturing Regulator Act mandates that “excess hydraulic fracturing flowback captured for temporary storage in a reserve pit as provided in paragraph (2) of this subsection must be removed from the well site within 7 days.” But Section 245.850 of the proposed rules states, “Any excess hydraulic fracturing flowback captured for temporary storage in a reserve pit as provided in Section 245.825 must be removed from the well site or transferred to storage in above-ground tanks for later disposal or recycling within 7 days after completion of high volume horizontal hydraulic fracturing operations.” Problem: The amendment of “after completion of high volume horizontal hydraulic fracturing operations” opens the door for the potential abuse of emergency pits. Storage in closed tanks can be costly for the industry. An unscrupulous operator wanting to cut costs could simply claim that there was more flowback than expected and end up using open pits for storage for the duration of the fracking process. The clear intent of the statute is to ensure that wastewater is stored in tanks except in the emergency event of an unforeseeable overflow, in which case it is preferable that the overflow go to a pit than simply spill on the ground. But in such event, the overflow is expressly required in the statute to be removed within a week. Through omission and misinterpretation, the regulations are not implementing this statutory directive. Section 245.210(a)(11), requires that an applicant submit a Hydraulic Fracturing Fluids and Flowback Plan. The plan does not include requirements to ensure that tank capacity is accurately calculated. Without such method, there is nothing in the regulations to prevent operators from underestimating the size of the tanks they need, so as to make routine use of the reserve pit for the resulting overflows. Operators presumably have an economic incentive to do so in order to hold down the cost of tank storage. Compounding this incentive is the Department’s weakening of the statutory directive that fluids deposited in a reserve pit be removed within 7 days (Section 1-75(c)(5)). The regulations fail to require such prompt removal, allowing, at subsection 245.850(c), the overflow to remain in the reserve pits until 7 days “after completion of high volume horizontal hydraulic fracturing operations.” Certainly on a multi-well pad, hydraulic fracturing operations can continue for a month or more, meaning that the flowback fluid could be left sitting in the reserve pit, creating environmental risk, for much longer than a week. An unscrupulous operator wanting to cut costs could simply claim that there was more flowback than expected and end up using open pits for storage for the duration of the fracking process. The clear intent of the statute is to ensure that wastewater is stored in tanks except in the emergency event of an unforeseeable overflow, in which case it is preferable that the overflow go to a pit than simply spill on the ground. But in such event, the overflow is expressly required in the statute to be removed within a week. Through omission and misinterpretation, the regulations are not implementing this statutory directive. Section 245.210(a)(11), requires that an applicant submit a Hydraulic Fracturing Fluids and Flowback Plan. The plan does not include requirements to ensure that tank capacity is accurately calculated. Without such method, there is nothing in the regulations to prevent operators from underestimating the size of the tanks they need, so as to make routine use of the reserve pit for the resulting overflows. Operators presumably have an economic incentive to do so in order to hold down the cost of tank storage. Compounding this incentive is the Department’s weakening of the statutory directive that fluids deposited in a reserve pit be removed within 7 days (Section 1-75(c)(5)). The regulations fail to require such prompt removal, allowing, at subsection 245.850(c), the overflow to remain in the reserve pits until 7 days “after completion of high volume horizontal hydraulic fracturing operations.” Certainly on a multi-well pad, hydraulic fracturing operations can continue for a month or more, meaning that the flowback fluid could be left sitting in the reserve pit, creating environmental risk, for much longer than a week. Revisions needed: First, require that drillers anticipate appropriate sized tanks for sufficient storage of flowback and produced water by establishing a method for tank capacity calculation. Second, clarify that wastewater must be removed from the pit within 7 days of the event that triggered the use of the pit rather than 7 days after fracking operations are complete, in accordance with the law.

Sincerely, William Toole Godfrey, IL 62035

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Section 1-75 of the Hydraulic Fracturing Regulator Act mandates that “excess hydraulic fracturing flowback captured for temporary storage in a reserve pit as provided in paragraph (2) of this subsection must be removed from the well site within 7 days.” But Section 245.850 of the proposed rules states, “Any excess hydraulic fracturing flowback captured for temporary storage in a reserve pit as provided in Section 245.825 must be removed from the well site or transferred to storage in above-ground tanks for later disposal or recycling within 7 days after completion of high volume horizontal hydraulic fracturing operations.” Problem: The amendment of “after completion of high volume horizontal hydraulic fracturing operations” opens the door for the potential abuse of emergency pits. Storage in closed tanks can be costly for the industry. An unscrupulous operator wanting to cut costs could simply claim that there was more flowback than expected and end up using open pits for storage for the duration of the fracking process. The clear intent of the statute is to ensure that wastewater is stored in tanks except in the emergency event of an unforeseeable overflow, in which case it is preferable that the overflow go to a pit than simply spill on the ground. But in such event, the overflow is expressly required in the statute to be removed within a week. In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Notably absent from these proposed rules is a requirement for the testing of "produced water", the fluid that returns from the well during the later stage of production (after flowback). Under the proposed rules, "produced water" can be stored on site and/or can be "recycled", yet there is no testing requirement. Naturally occurring radioactive material (NORM) is found in "produced water" also. See Technologically enhanced naturally occurring radioactive materials in the oil industry (TENORM), Nukleonika 2009; 54(1):3-9, and sources cited therein, especially for TENORM in produced water in the U.S., available at [http://www.nukleonika.pl/www/back/full/vol54\\_2009/v54n1p003f.pdf](http://www.nukleonika.pl/www/back/full/vol54_2009/v54n1p003f.pdf). See also NORM is also found on scale in oil pipes and on fracking equipment. (See Kentucky Resources Council Proposes Comprehensive Plan For Investigating Radiological Contamination In Martha Oil Field. August 11, 2005. <http://www.kyrc.org/webnewspro/112381723236086.shtml>.) IDNR's definitions of "flowback water" and "produced water" are different. The two are distinguishably different enough that they are treated as separate types of fluid by both the Hydraulic Fracturing Regulatory Act and by the DNR Rules. Discharge of produced water onto the ground or into surface water or water drainage way is prohibited but it is not tested for radioactivity. This despite the fact that this fluid will be in contact with the naturally occurring radioactive elements in the ground for a longer period than the flowback and that it is much more likely to be radioactive. Problems: Failure to test produced water for radioactivity is problematic for a variety of reasons including: The health and safety of workers on the site who will be unaware of the levels of radioactivity they are being exposed to. The health and safety of workers transporting produced water who will also be in the dark regarding the levels of radioactivity they will be exposed to. The risk of storing radioactive material in tanks not created for storing radioactive materials. The risk of "recycling" produced water—radioactivity cannot be removed by recycling. The risk to the public in transporting radioactive materials Argonne National Laboratory recently cautioned about radiological doses: "It is commonly accepted that efforts should be undertaken at all times to keep radiological doses 'as low as reasonably achievable,' which is referred to as the ALARA principle or requirement." Overview of Radiological Dose and Risk Assessment (April 2011). DNR is failing to even adequately test for radioactivity and therefore, will not know the levels of radioactivity. How, then, can DNR adequately protect workers and the general public? Revisions needed: At a bare minimum, the rules should require that "produced water" be tested at two separate intervals across time for radioactivity. This is already required in Pennsylvania. The rules should also require that the requirements of the Illinois Low Level Radioactivity Waste Management Act be followed.

Sincerely, Brenna Moss Chicago, IL 60605

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Problem: The limited radioactivity testing requirement in this section does not adequately protect Illinois residents from the spread of dangerous radioactive materials. The statute and the proposed rule call for the testing of flowback (and not produced water) for "naturally occurring radioactive materials". However, the term "naturally occurring" is not defined in the statute or the proposed rules; DNR could interpret the quoted term so that testing will be required only for the specific radioactive materials that are expected to be found naturally in the subsurface at the well site. Depleted uranium would not be "naturally occurring" at the well site, so it will be undetected by the proposed testing. Depleted uranium (DU) is a highly dangerous radioactive material with a half-life of 4.5 billion years. It is a waste product left over when uranium is modified to produce fissionable material for nuclear reactors and weapons. We know that at least one of the major actors in the fracking industry has incorporated Depleted Uranium into its plan for perforating the gun assembly (for use in a wellbore) in horizontal fracturing operations. (See U.S. Patent No. 2011000069, "perforating gun assembly for use in a wellbore \*\*\* wherein the secondary pressure generator is selected from the group consisting of \*\*\* depleted uranium"; assignee of patent: Halliburton Energy Services, Inc.) Note that, in this case, radioactive material would be "added" radioactive material, not "naturally occurring." The General Assembly (implicitly) granted IDNR the authority to define "radioactivity." Radioactivity is a many splendored thing and comes in four major flavors: uranium 238, radium 226 and radium 228, and radon222. Each of these poses its own risks to our soil, water--and radon levels in our kitchens. So, will IDNR mandate testing for all four? Three? Two? One? The rule does not say. Revisions Needed: In order to protect the public health and safety and to preserve the health of our environment, DNR must require specific testing for DU among other types of radioactive material in flowback and in produced water and set standards and requirements for when radioactivity is found. Also IDNR should test for uranium238, radium226 and radium228 in flowback/produced water, drill cuttings, storage and reserve pit areas. Test for radium 226 and radium 228 in pipes and equipment, and radon222 at the wellhead.

Sincerely, Abby Dompke Chicago, IL 60607

Revisions Needed: In order to protect the public health and safety and to preserve the health of our environment, DNR must require specific testing for DU among other types of radioactive material in flowback and in produced water and set standards and requirements for when radioactivity is found. Also IDNR should test for uranium238, radium226 and radium228 in flowback/produced water, drill cuttings, storage and reserve pit areas. Test for radium 226 and radium 228 in pipes and equipment, and radon222 at the wellhead.

Sincerely, Alyssa Carabez Carabez Brookfield, IL 60573

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Problem: The limited radioactivity testing requirement in this section does not adequately protect Illinois residents from the spread of dangerous radioactive materials. The statute and the proposed rule call for the testing of flowback (and not produced water) for "naturally occurring radioactive materials". However, the term "naturally occurring" is not defined in the statute or the proposed rules; DNR could interpret the quoted term so that testing will be required only for the specific radioactive materials that are expected to be found naturally in the subsurface at the well site. Depleted uranium would not be "naturally occurring" at the well site, so it will be undetected by the proposed testing. Depleted uranium (DU) is a highly dangerous radioactive material with a half-life of 4.5 billion years. It is a waste product left over when uranium is modified to produce fissionable material for nuclear reactors and weapons. We know that at least one of the major actors in the fracking industry has incorporated Depleted Uranium into its plan for perforating the gun assembly (for use in a wellbore) in horizontal fracturing operations. (See U.S. Patent No. 2011000069, "perforating gun assembly for use in a wellbore \*\*\* wherein the secondary pressure generator is selected from the group consisting of \*\*\* depleted uranium"; assignee of patent: Halliburton Energy Services, Inc.) Note that, in this case, radioactive material would be "added" radioactive material, not "naturally occurring." The General Assembly (implicitly) granted IDNR the authority to define "radioactivity." Radioactivity is a many splendored thing and comes in four major flavors: uranium 238, radium 226 and radium 228, and radon222. Each of these poses its own risks to our soil, water--and radon levels in our kitchens. So, will IDNR mandate testing for all four? Three? Two? One? The rule does not say. Revisions Needed: In order to protect the public health and safety and to preserve the health of our environment, DNR must require specific testing for DU among other types of radioactive material in flowback and in produced water and set standards and requirements for when radioactivity is found. Also IDNR should test for uranium238, radium226 and radium228 in flowback/produced water, drill cuttings, storage and reserve pit areas. In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Problem: The limited radioactivity testing requirement in this section does not adequately protect Illinois residents from the spread of dangerous radioactive materials. The statute and the proposed rule call for the testing of flowback (and not produced water) for "naturally occurring radioactive materials". However, the term "naturally occurring" is not defined in the statute or the proposed rules; DNR could interpret the quoted term so that testing will be required only for the specific radioactive materials that are expected to be found naturally in the subsurface at the well site. Depleted uranium would not be "naturally occurring" at the well site, so it will be undetected by the proposed testing. Depleted uranium (DU) is a highly dangerous radioactive material with a half-life of 4.5 billion years. It is a waste product left over when uranium is modified to produce fissionable material for nuclear reactors and weapons. We know that at least one of the major actors in the fracking industry has incorporated Depleted Uranium into its plan for perforating the gun assembly (for use in a wellbore) in horizontal fracturing operations. (See U.S. Patent No. 2011000069, "perforating gun assembly for use in a wellbore \*\*\* wherein the secondary pressure generator is selected from the group consisting of \*\*\* depleted uranium"; assignee of patent: Halliburton Energy Services, Inc.) Note that, in this case, radioactive material would be "added" radioactive material, not "naturally occurring." Revisions Needed: In order to protect the public health and safety and to preserve the health of our environment, DNR must require specific testing for DU among other types of radioactive material in flowback and in produced water and set standards and requirements for when radioactivity is found.

Sincerely, Baylee Champion Chicago, IL 60616

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Problem: The limited radioactivity testing requirement in this section does not adequately protect Illinois residents from the spread of dangerous radioactive materials. The statute and the proposed rule call for the testing of flowback (and not produced water) for "naturally occurring radioactive materials". However, the term "naturally occurring" is not defined in the statute or the proposed rules; DNR could interpret the quoted term so that testing will be required only for the specific radioactive materials that are expected to be found naturally in the subsurface at the well site. Depleted uranium would not be "naturally occurring" at the well site, so it will be undetected by the proposed testing. Depleted uranium (DU) is a highly dangerous radioactive material with a half-life of 4.5 billion years. It is a waste product left over when uranium is modified to produce fissionable material for nuclear reactors and weapons. We know that at least one of the major actors in the fracking industry has incorporated Depleted Uranium into its plan for perforating the gun assembly (for use in a wellbore) in horizontal fracturing operations. (See U.S. Patent No. 2011000069, "perforating gun assembly for use in a wellbore \*\*\* wherein the secondary pressure generator is selected from the group consisting of \*\*\* depleted uranium"; assignee of patent: Halliburton Energy Services, Inc.) Note that, in this case, radioactive material would be "added" radioactive material, not "naturally occurring." The General Assembly (implicitly) granted IDNR the authority to define "radioactivity." Radioactivity is a many splendored thing and comes in four major flavors: uranium 238, radium 226 and radium 228, and radon222. Each of these poses its own risks to our soil, water--and radon levels in our kitchens. So, will IDNR mandate testing for all four? Three? Two? One? The rule does not say. Revisions Needed: In order to protect the public health and safety and to preserve the health of our environment, DNR must require specific testing for DU among other types of radioactive material in flowback and in produced water and set standards and requirements for when radioactivity is found. Also IDNR should test for uranium238, radium226 and radium228 in flowback/produced water, drill cuttings, storage and reserve pit areas. Test for radium 226 and radium 228 in pipes and equipment, and radon222 at the wellhead.

Sincerely, Benjamin Chametzky Chicago, IL 60637

It is a waste product left over when uranium is modified to produce fissionable material for nuclear reactors and weapons. We know that at least one of the major actors in the fracking industry has incorporated Depleted Uranium into its plan for perforating the gun assembly (for use in a wellbore) in horizontal fracturing operations. (See U.S. Patent No. 2011000069, "perforating gun assembly for use in a wellbore \*\*\* wherein the secondary pressure generator is selected from the group consisting of \*\*\* depleted uranium"; assignee of patent: Halliburton Energy Services, Inc.) Note that, in this case, radioactive material would be "added" radioactive material, not "naturally occurring." The General Assembly (implicitly) granted IDNR the authority to define "radioactivity." Radioactivity is a many splendored thing and comes in four major flavors: uranium 238, radium 226 and radium 228, and radon222. Each of these poses its own risks to our soil, water--and radon levels in our kitchens. So, will IDNR mandate testing for all four? Three? Two? One? The rule does not say. Revisions Needed: In order to protect the public health and safety and to preserve the health of our environment, DNR must require specific testing for DU among other types of radioactive material in flowback and in produced water and set standards and requirements for when radioactivity is found. Also IDNR should test for uranium238, radium226 and radium228 in flowback/produced water, drill cuttings, storage and reserve pit areas. Test for radium 226 and radium 228 in pipes and equipment, and radon222 at the wellhead.

Sincerely, Christian Mortensen Chicago, IL 60637

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Problem: The limited radioactivity testing requirement in this section does not adequately protect Illinois residents from the spread of dangerous radioactive materials. The statute and the proposed rule call for the testing of flowback (and not produced water) for "naturally occurring radioactive materials". However, the term "naturally occurring" is not defined in the statute or the proposed rules; DNR could interpret the quoted term so that testing will be required only for the specific radioactive materials that are expected to be found naturally in the subsurface at the well site. Depleted uranium would not be "naturally occurring" at the well site, so it will be undetected by the proposed testing. Depleted uranium (DU) is a highly dangerous radioactive material with a half-life of 4.5 billion years. It is a waste product left over when uranium is modified to produce fissionable material for nuclear reactors and weapons. We know that at least one of the major actors in the fracking industry has incorporated Depleted Uranium into its plan for perforating the gun assembly (for use in a wellbore) in horizontal fracturing operations. (See U.S. Patent No. 2011000069, "perforating gun assembly for use in a wellbore \*\*\* wherein the secondary pressure generator is selected from the group consisting of \*\*\* depleted uranium"; assignee of patent: Halliburton Energy Services, Inc.) Revisions Needed: In order to protect the public health and safety and to preserve the health of our environment, DNR must require specific testing for DU among other types of radioactive material in flowback and in produced water and set standards and requirements for when radioactivity is found. Also IDNR should test for uranium238, radium226 and radium228 in flowback/produced water, drill cuttings, storage and reserve pit areas. Test for radium 226 and radium 228 in pipes and equipment, and radon222 at the wellhead.

Sincerely, Durango Mendoza Urbana, IL 61801

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Problem: The limited radioactivity testing requirement in this section does not adequately protect Illinois residents from the spread of dangerous radioactive materials. The statute and the proposed rule call for the testing of flowback (and not produced water) for "naturally occurring radioactive materials". However, the term "naturally occurring" is not defined in the statute or the proposed rules; DNR could interpret the quoted term so that testing will be required only for the specific radioactive materials that are expected to be found naturally in the subsurface at the well site. Depleted uranium would not be "naturally occurring" at the well site, so it will be undetected by the proposed testing. Depleted uranium (DU) is a highly dangerous radioactive material with a half-life of 4.5 billion years. It is a waste product left over when uranium is modified to produce fissionable material for nuclear reactors and weapons. We know that at least one of the major actors in the fracking industry has incorporated Depleted Uranium into its plan for perforating the gun assembly (for use in a wellbore) in horizontal fracturing operations. (See U.S. Patent No. 2011000069, "perforating gun assembly for use in a wellbore \*\*\* wherein the secondary pressure generator is selected from the group consisting of \*\*\* depleted uranium"; assignee of patent: Halliburton Energy Services, Inc.) Note that, in this case, radioactive material would be "added" radioactive material, not "naturally occurring." The General Assembly (implicitly) granted IDNR the authority to define "radioactivity." Radioactivity is a many splendored thing and comes in four major flavors: uranium 238, radium 226 and radium 228, and radon222. Each of these poses its own risks to our soil, water--and radon levels in our kitchens. So, will IDNR mandate testing for all four? Three? Two? One? The rule does not say. Revisions Needed: In order to protect the public health and safety and to preserve the health of our environment, DNR must require specific testing for DU among other types of radioactive material in flowback and in produced water and set standards and requirements for when radioactivity is found. Also IDNR should test for uranium238, radium226 and radium228 in flowback/produced water, drill cuttings, storage and reserve pit areas. Test for radium 226 and radium 228 in pipes and equipment, and radon222 at the wellhead.

It is a waste product left over when uranium is modified to produce fissionable material for nuclear reactors and weapons. We know that at least one of the major actors in the fracking industry has incorporated Depleted Uranium into its plan for perforating the gun assembly (for use in a wellbore) in horizontal fracturing operations. (See U.S. Patent No. 2011000069, "perforating gun assembly for use in a wellbore \*\*\* wherein the secondary pressure generator is selected from the group consisting of \*\*\* depleted uranium"; assignee of patent: Halliburton Energy Services, Inc.) Note that, in this case, radioactive material would be "added" radioactive material, not "naturally occurring." The General Assembly (implicitly) granted IDNR the authority to define "radioactivity." Radioactivity is a many splendored thing and comes in four major flavors: uranium 238, radium 226 and radium 228, and radon222. Each of these poses its own risks to our soil, water--and radon levels in our kitchens. So, will IDNR mandate testing for all four? Three? Two? One? The rule does not say. Revisions Needed: In order to protect the public health and safety and to preserve the health of our environment, DNR must require specific testing for DU among other types of radioactive material in flowback and in produced water and set standards and requirements for when radioactivity is found. Also IDNR should test for uranium238, radium226 and radium228 in flowback/produced water, drill cuttings, storage and reserve pit areas. Test for radium 226 and radium 228 in pipes and equipment, and radon222 at the wellhead.

Sincerely, Frank Pettis Chicago, IL 60605

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Problem: The limited radioactivity testing requirement in this section does not adequately protect Illinois residents from the spread of dangerous radioactive materials. The statute and the proposed rule call for the testing of flowback (and not produced water) for "naturally occurring radioactive materials". However, the term "naturally occurring" is not defined in the statute or the proposed rules; DNR could interpret the quoted term so that testing will be required only for the specific radioactive materials that are expected to be found naturally in the subsurface at the well site. Depleted uranium would not be "naturally occurring" at the well site, so it will be undetected by the proposed testing. Depleted uranium (DU) is a highly dangerous radioactive material with a half-life of 4.5 billion years. It is a waste product left over when uranium is modified to produce fissionable material for nuclear reactors and weapons. We know that at least one of the major actors in the fracking industry has incorporated Depleted Uranium into its plan for perforating the gun assembly (for use in a wellbore) in horizontal fracturing operations. (See U.S. Patent No. 2011000069, "perforating gun assembly for use in a wellbore \*\*\* wherein the secondary pressure generator is selected from the group consisting of \*\*\* depleted uranium"; assignee of patent: Halliburton Energy Services, Inc.) Revisions Needed: In order to protect the public health and safety and to preserve the health of our environment, DNR must require specific testing for DU among other types of radioactive material in flowback and in produced water and set standards and requirements for when radioactivity is found. Also IDNR should test for uranium238, radium226 and radium228 in flowback/produced water, drill cuttings, storage and reserve pit areas. Test for radium 226 and radium 228 in pipes and equipment, and radon222 at the wellhead.

Sincerely, Jay Chicago, IL 60637

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Problem: The limited radioactivity testing requirement in this section does not adequately protect Illinois residents from the spread of dangerous radioactive materials. The statute and the proposed rule call for the testing of flowback (and not produced water) for "naturally occurring radioactive materials". However, the term "naturally occurring" is not defined in the statute or the proposed rules; DNR could interpret the quoted term so that testing will be required only for the specific radioactive materials that are expected to be found naturally in the subsurface at the well site. Depleted uranium would not be "naturally occurring" at the well site, so it will be undetected by the proposed testing. Depleted uranium (DU) is a highly dangerous radioactive material with a half-life of 4.5 billion years. It is a waste product left over when uranium is modified to produce fissionable material for nuclear reactors and weapons. We know that at least one of the major actors in the fracking industry has incorporated Depleted Uranium into its plan for perforating the gun assembly (for use in a wellbore) in horizontal fracturing operations. (See U.S. Patent No. 2011000069, "perforating gun assembly for use in a wellbore \*\*\* wherein the secondary pressure generator is selected from the group consisting of \*\*\* depleted uranium"; assignee of patent: Halliburton Energy Services, Inc.) Note that, in this case, radioactive material would be "added" radioactive material, not "naturally occurring." Revisions Needed: In order to protect the public health and safety and to preserve the health of our environment, DNR must require specific testing for DU among other types of radioactive material in flowback and in produced water and set standards and requirements for when radioactivity is found.

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Problem: The limited radioactivity testing requirement in this section does not adequately protect Illinois residents from the spread of dangerous radioactive materials. The statute and the proposed rule call for the testing of flowback (and not produced water) for "naturally occurring radioactive materials". However, the term "naturally occurring" is not defined in the statute or the proposed rules; DNR could interpret the quoted term so that testing will be required only for the specific radioactive materials that are expected to be found naturally in the subsurface at the well site. Depleted uranium would not be "naturally occurring" at the well site, so it will be undetected by the proposed testing. Depleted uranium (DU) is a highly dangerous radioactive material with a half-life of 4.5 billion years. It is a waste product left over when uranium is modified to produce fissionable material for nuclear reactors and weapons. We know that at least one of the major actors in the fracking industry has incorporated Depleted Uranium into its plan for perforating the gun assembly (for use in a wellbore) in horizontal fracturing operations. (See U.S. Patent No. 2011000069, "perforating gun assembly for use in a wellbore \*\*\* wherein the secondary pressure generator is selected from the group consisting of \*\*\* depleted uranium"; assignee of patent: Halliburton Energy Services, Inc.) Note that, in this case, radioactive material would be "added" radioactive material, not "naturally occurring." The General Assembly (implicitly) granted IDNR the authority to define "radioactivity." Radioactivity is a many splendored thing and comes in four major flavors: uranium 238, radium 226 and radium 228, and radon222. Each of these poses its own risks to our soil, water--and radon levels in our kitchens. So, will IDNR mandate testing for all four? Three? Two? One? The rule does not say. Revisions Needed: In order to protect the public health and safety and to preserve the health of our environment, DNR must require specific testing for DU among other types of radioactive material in flowback and in produced water and set standards and requirements for when radioactivity is found. Also IDNR should test for uranium238, radium226 and radium228 in flowback/produced water, drill cuttings, storage and reserve pit areas. Test for radium 226 and radium 228 in pipes and equipment, and radon222 at the wellhead.

Sincerely, John Hunt Chicago, IL 60641

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Problem: The limited radioactivity testing requirement in this section does not adequately protect Illinois residents from the spread of dangerous radioactive materials. The statute and the proposed rule call for the testing of flowback (and not produced water) for "naturally occurring radioactive materials". However, the term "naturally occurring" is not defined in the statute or the proposed rules; DNR could interpret the quoted term so that testing will be required only for the specific radioactive materials that are expected to be found naturally in the subsurface at the well site. Depleted uranium would not be "naturally occurring" at the well site, so it will be undetected by the proposed testing. Depleted uranium (DU) is a highly dangerous radioactive material with a half-life of 4.5 billion years. It is a waste product left over when uranium is modified to produce fissionable material for nuclear reactors and weapons. We know that at least one of the major actors in the fracking industry has incorporated Depleted Uranium into its plan for perforating the gun assembly (for use in a wellbore) in horizontal fracturing operations. (See U.S. Patent No. 2011000069, "perforating gun assembly for use in a wellbore \*\*\* wherein the secondary pressure generator is selected from the group consisting of \*\*\* depleted uranium"; assignee of patent: Halliburton Energy Services, Inc.) Note that, in this case, radioactive material would be "added" radioactive material, not "naturally occurring." The General Assembly (implicitly) granted IDNR the authority to define "radioactivity." Radioactivity is a many splendored thing and comes in four major flavors: uranium 238, radium 226 and radium 228, and radon222. Each of these poses its own risks to our soil, water--and radon levels in our kitchens. So, will IDNR mandate testing for all four? Three? Two? One? The rule does not say. Revisions Needed: In order to protect the public health and safety and to preserve the health of our environment, DNR must require specific testing for DU among other types of radioactive material in flowback and in produced water and set standards and requirements for when radioactivity is found. Also IDNR should test for uranium238, radium226 and radium228 in flowback/produced water, drill cuttings, storage and reserve pit areas. Test for radium 226 and radium 228 in pipes and equipment, and radon222 at the wellhead.

Sincerely, Kayli Horne Chicago, IL 60615

The statute and the proposed rule call for the testing of flowback (and not produced water) for "naturally occurring radioactive materials". However, the term "naturally occurring" is not defined in the statute or the proposed rules; DNR could interpret the quoted term so that testing will be required only for the specific radioactive materials that are expected to be found naturally in the subsurface at the well site. Depleted uranium would not be "naturally occurring" at the well site, so it will be undetected by the proposed testing. Depleted uranium (DU) is a highly dangerous radioactive material with a half-life of 4.5 billion years. It is a waste product left over when uranium is modified to produce fissionable material for nuclear reactors and weapons. We know that at least one of the major actors in the fracking industry has incorporated Depleted Uranium into its plan for perforating the gun assembly (for use in a wellbore) in horizontal fracturing operations. (See U.S. Patent No. 2011000069, "perforating gun assembly for use in a wellbore \*\*\* wherein the secondary pressure generator is selected from the group consisting of \*\*\* depleted uranium"; assignee of patent: Halliburton Energy Services, Inc.) Note that, in this case, radioactive material would be "added" radioactive material, not "naturally occurring." The General Assembly (implicitly) granted IDNR the authority to define "radioactivity." Radioactivity is a many splendored thing and comes in four major flavors: uranium 238, radium 226 and radium 228, and radon222. Each of these poses its own risks to our soil, water--and radon levels in our kitchens. So, will IDNR mandate testing for all four? Three? Two? One? The rule does not say. Revisions Needed: In order to protect the public health and safety and to preserve the health of our environment, DNR must require specific testing for DU among other types of radioactive material in flowback and in produced water and set standards and requirements for when radioactivity is found. Also IDNR should test for uranium238, radium226 and radium228 in flowback/produced water, drill cuttings, storage and reserve pit areas. Test for radium 226 and radium 228 in pipes and equipment, and radon222 at the wellhead.

Sincerely, Louis Clark Chicago, IL 60637

Note that, in this case, radioactive material would be "added" radioactive material, not "naturally occurring." The General Assembly (implicitly) granted IDNR the authority to define "radioactivity." Radioactivity is a many splendored thing and comes in four major flavors: uranium 238, radium 226 and radium 228, and radon222. Each of these poses its own risks to our soil, water--and radon levels in our kitchens. So, will IDNR mandate testing for all four? Three? Two? One? The rule does not say. Revisions Needed: In order to protect the public health and safety and to preserve the health of our environment, DNR must require specific testing for DU among other types of radioactive material in flowback and in produced water and set standards and requirements for when radioactivity is found. Also IDNR should test for uranium238, radium226 and radium228 in flowback/produced water, drill cuttings, storage and reserve pit areas. Test for radium 226 and radium 228 in pipes and equipment, and radon222 at the wellhead.

Sincerely, Mary Trimmer Granite City, IL 62040

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Problem: The limited radioactivity testing requirement in this section does not adequately protect Illinois residents from the spread of dangerous radioactive materials. The statute and the proposed rule call for the testing of flowback (and not produced water) for "naturally occurring radioactive materials". However, the term "naturally occurring" is not defined in the statute or the proposed rules; DNR could interpret the quoted term so that testing will be required only for the specific radioactive materials that are expected to be found naturally in the subsurface at the well site. Depleted uranium would not be "naturally occurring" at the well site, so it will be undetected by the proposed testing. Depleted uranium (DU) is a highly dangerous radioactive material with a half-life of 4.5 billion years. It is a waste product left over when uranium is modified to produce fissionable material for nuclear reactors and weapons. We know that at least one of the major actors in the fracking industry has incorporated Depleted Uranium into its plan for perforating the gun assembly (for use in a wellbore) in horizontal fracturing operations. (See U.S. Patent No. 2011000069, "perforating gun assembly for use in a wellbore \*\*\* wherein the secondary pressure generator is selected from the group consisting of \*\*\* depleted uranium"; assignee of patent: Halliburton Energy Services, Inc.) Note that, in this case, radioactive material would be "added" radioactive material, not "naturally occurring." Revisions Needed: In order to protect the public health and safety and to preserve the health of our environment, DNR must require specific testing for DU among other types of radioactive material in flowback and in produced water and set standards and requirements for when radioactivity is found.

Depleted uranium (DU) is a highly dangerous radioactive material with a half-life of 4.5 billion years. It is a waste product left over when uranium is modified to produce fissionable material for nuclear reactors and weapons. We know that at least one of the major actors in the fracking industry has incorporated Depleted Uranium into its plan for perforating the gun assembly (for use in a wellbore) in horizontal fracturing operations. (See U.S. Patent No. 2011000069, "perforating gun assembly for use in a wellbore \*\*\* wherein the secondary pressure generator is selected from the group consisting of \*\*\* depleted uranium"; assignee of patent: Halliburton Energy Services, Inc.) Note that, in this case, radioactive material would be "added" radioactive material, not "naturally occurring." The General Assembly (implicitly) granted IDNR the authority to define "radioactivity." Radioactivity is a many splendored thing and comes in four major flavors: uranium 238, radium 226 and radium 228, and radon222. Each of these poses its own risks to our soil, water--and radon levels in our kitchens. So, will IDNR mandate testing for all four? Three? Two? One? The rule does not say. Revisions Needed: In order to protect the public health and safety and to preserve the health of our environment, DNR must require specific testing for DU among other types of radioactive material in flowback and in produced water and set standards and requirements for when radioactivity is found. Also IDNR should test for uranium238, radium226 and radium228 in flowback/produced water, drill cuttings, storage and reserve pit areas. Test for radium 226 and radium 228 in pipes and equipment, and radon222 at the wellhead.

Sincerely, Navroz Tharani Chicago, IL 60615

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Problem: The limited radioactivity testing requirement in this section does not adequately protect Illinois residents from the spread of dangerous radioactive materials. The statute and the proposed rule call for the testing of flowback (and not produced water) for "naturally occurring radioactive materials". However, the term "naturally occurring" is not defined in the statute or the proposed rules; DNR could interpret the quoted term so that testing will be required only for the specific radioactive materials that are expected to be found naturally in the subsurface at the well site. Depleted uranium would not be "naturally occurring" at the well site, so it will be undetected by the proposed testing. Depleted uranium (DU) is a highly dangerous radioactive material with a half-life of 4.5 billion years. It is a waste product left over when uranium is modified to produce fissionable material for nuclear reactors and weapons. We know that at least one of the major actors in the fracking industry has incorporated Depleted Uranium into its plan for perforating the gun assembly (for use in a wellbore) in horizontal fracturing operations. Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Problem: The limited radioactivity testing requirement in this section does not adequately protect Illinois residents from the spread of dangerous radioactive materials. The statute and the proposed rule call for the testing of flowback (and not produced water) for "naturally occurring radioactive materials". However, the term "naturally occurring" is not defined in the statute or the proposed rules; DNR could interpret the quoted term so that testing will be required only for the specific radioactive materials that are expected to be found naturally in the subsurface at the well site. Depleted uranium would not be "naturally occurring" at the well site, so it will be undetected by the proposed testing. Depleted uranium (DU) is a highly dangerous radioactive material with a half-life of 4.5 billion years. It is a waste product left over when uranium is modified to produce fissionable material for nuclear reactors and weapons. We know that at least one of the major actors in the fracking industry has incorporated Depleted Uranium into its plan for perforating the gun assembly (for use in a wellbore) in horizontal fracturing operations. (See U.S. Patent No. 2011000069, "perforating gun assembly for use in a wellbore \*\*\* wherein the secondary pressure generator is selected from the group consisting of \*\*\* depleted uranium"; assignee of patent: Halliburton Energy Services, Inc.) Note that, in this case, radioactive material would be "added" radioactive material, not "naturally occurring." The General Assembly (implicitly) granted IDNR the authority to define "radioactivity." Radioactivity is a many splendored thing and comes in four major flavors: uranium 238, radium 226 and radium 228, and radon222. Each of these poses its own risks to our soil, water--and radon levels in our kitchens. So, will IDNR mandate testing for all four? Three? Two? One? The rule does not say. Revisions Needed: In order to protect the public health and safety and to preserve the health of our environment, DNR must require specific testing for DU among other types of radioactive material in flowback and in produced water and set standards and requirements for when radioactivity is found. Also IDNR should test for uranium238, radium226 and radium228 in flowback/produced water, drill cuttings, storage and reserve pit areas. Test for radium 226 and radium 228 in pipes and equipment, and radon222 at the wellhead.

Sincerely, Rachael Dompke Belleville, IL 62221

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Problem: The limited radioactivity testing requirement in this section does not adequately protect Illinois residents from the spread of dangerous radioactive materials. The statute and the proposed rule call for the testing of flowback (and not produced water) for "naturally occurring radioactive materials". However, the term "naturally occurring" is not defined in the statute or the proposed rules; DNR could interpret the quoted term so that testing will be required only for the specific radioactive materials that are expected to be found naturally in the subsurface at the well site. Depleted uranium would not be "naturally occurring" at the well site, so it will be undetected by the proposed testing. Depleted uranium (DU) is a highly dangerous radioactive material with a half-life of 4.5 billion years. It is a waste product left over when uranium is modified to produce fissionable material for nuclear reactors and weapons. We know that at least one of the major actors in the fracking industry has incorporated Depleted Uranium into its plan for perforating the gun assembly (for use in a wellbore) in horizontal fracturing operations. (See U.S. Patent No. 2011000069, "perforating gun assembly for use in a wellbore \*\*\* wherein the secondary pressure generator is selected from the group consisting of \*\*\* depleted uranium"; assignee of patent: Halliburton Energy Services, Inc.) Note that, in this case, radioactive material would be "added" radioactive material, not "naturally occurring." The General Assembly (implicitly) granted IDNR the authority to define "radioactivity." Radioactivity is a many splendored thing and comes in four major flavors: uranium 238, radium 226 and radium 228, and radon222. Each of these poses its own risks to our soil, water--and radon levels in our kitchens. So, will IDNR mandate testing for all four? Three? Two? One? The rule does not say. Revisions Needed: In order to protect the public health and safety and to preserve the health of our environment, DNR must require specific testing for DU among other types of radioactive material in flowback and in produced water and set standards and requirements for when radioactivity is found. Also IDNR should test for uranium238, radium226 and radium228 in flowback/produced water, drill cuttings, storage and reserve pit areas. Test for radium 226 and radium 228 in pipes and equipment, and radon222 at the wellhead.

Sincerely, Rebecca Quesnell Chicago, IL 60605

It is a waste product left over when uranium is modified to produce fissionable material for nuclear reactors and weapons. We know that at least one of the major actors in the fracking industry has incorporated Depleted Uranium into its plan for perforating the gun assembly (for use in a wellbore) in horizontal fracturing operations. (See U.S. Patent No. 2011000069, "perforating gun assembly for use in a wellbore \*\*\* wherein the secondary pressure generator is selected from the group consisting of \*\*\* depleted uranium"; assignee of patent: Halliburton Energy Services, Inc.) Note that, in this case, radioactive material would be "added" radioactive material, not "naturally occurring." The General Assembly (implicitly) granted IDNR the authority to define "radioactivity." Radioactivity is a many splendored thing and comes in four major flavors: uranium 238, radium 226 and radium 228, and radon222. Each of these poses its own risks to our soil, water--and radon levels in our kitchens. So, will IDNR mandate testing for all four? Three? Two? One? The rule does not say. Revisions Needed: In order to protect the public health and safety and to preserve the health of our environment, DNR must require specific testing for DU among other types of radioactive material in flowback and in produced water and set standards and requirements for when radioactivity is found. Also IDNR should test for uranium238, radium226 and radium228 in flowback/produced water, drill cuttings, storage and reserve pit areas. Test for radium 226 and radium 228 in pipes and equipment, and radon222 at the wellhead.

Sincerely, Sara Buck Chicago, IL 60640

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Problem: The limited radioactivity testing requirement in this section does not adequately protect Illinois residents from the spread of dangerous radioactive materials. The statute and the proposed rule call for the testing of flowback (and not produced water) for "naturally occurring radioactive materials". However, the term "naturally occurring" is not defined in the statute or the proposed rules; DNR could interpret the quoted term so that testing will be required only for the specific radioactive materials that are expected to be found naturally in the subsurface at the well site. Depleted uranium would not be "naturally occurring" at the well site, so it will be undetected by the proposed testing. Depleted uranium (DU) is a highly dangerous radioactive material with a half-life of 4.5 billion years. It is a waste product left over when uranium is modified to produce fissionable material for nuclear reactors and weapons. We know that at least one of the major actors in the fracking industry has incorporated Depleted Uranium into its plan for perforating the gun assembly (for use in a wellbore) in horizontal fracturing operations. (See U.S. Patent No. 2011000069, "perforating gun assembly for use in a wellbore \*\*\* wherein the secondary pressure generator is selected from the group consisting of \*\*\* depleted uranium"; assignee of patent: Halliburton Energy Services, Inc.) Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Problem: The limited radioactivity testing requirement in this section does not adequately protect Illinois residents from the spread of dangerous radioactive materials. The statute and the proposed rule call for the testing of flowback (and not produced water) for "naturally occurring radioactive materials". However, the term "naturally occurring" is not defined in the statute or the proposed rules; DNR could interpret the quoted term so that testing will be required only for the specific radioactive materials that are expected to be found naturally in the subsurface at the well site. Depleted uranium would not be "naturally occurring" at the well site, so it will be undetected by the proposed testing. Depleted uranium (DU) is a highly dangerous radioactive material with a half-life of 4.5 billion years. It is a waste product left over when uranium is modified to produce fissionable material for nuclear reactors and weapons. We know that at least one of the major actors in the fracking industry has incorporated Depleted Uranium into its plan for perforating the gun assembly (for use in a wellbore) in horizontal fracturing operations. (See U.S. Patent No. 2011000069, "perforating gun assembly for use in a wellbore \*\*\* wherein the secondary pressure generator is selected from the group consisting of \*\*\* depleted uranium"; assignee of patent: Halliburton Energy Services, Inc.) Note that, in this case, radioactive material would be "added" radioactive material, not "naturally occurring." The General Assembly (implicitly) granted IDNR the authority to define "radioactivity." Radioactivity is a many splendored thing and comes in four major flavors: uranium 238, radium 226 and radium 228, and radon222. Each of these poses its own risks to our soil, water--and radon levels in our kitchens. So, will IDNR mandate testing for all four? Three? Two? One? The rule does not say. Revisions Needed: In order to protect the public health and safety and to preserve the health of our environment, DNR must require specific testing for DU among other types of radioactive material in flowback and in produced water and set standards and requirements for when radioactivity is found. Also IDNR should test for uranium238, radium226 and radium228 in flowback/produced water, drill cuttings, storage and reserve pit areas. Test for radium 226 and radium 228 in pipes and equipment, and radon222 at the wellhead.

Sincerely, Shawn Mukherji Chicago, IL 60605

We know that at least one of the major actors in the fracking industry has incorporated Depleted Uranium into its plan for perforating the gun assembly (for use in a wellbore) in horizontal fracturing operations. (See U.S. Patent No. 2011000069, "perforating gun assembly for use in a wellbore \*\*\* wherein the secondary pressure generator is selected from the group consisting of \*\*\* depleted uranium"; assignee of patent: Halliburton Energy Services, Inc.) Note that, in this case, radioactive material would be "added" radioactive material, not "naturally occurring." The General Assembly (implicitly) granted IDNR the authority to define "radioactivity." Radioactivity is a many splendored thing and comes in four major flavors: uranium 238, radium 226 and radium 228, and radon222. Each of these poses its own risks to our soil, water--and radon levels in our kitchens. So, will IDNR mandate testing for all four? Three? Two? One? The rule does not say. Revisions Needed: In order to protect the public health and safety and to preserve the health of our environment, DNR must require specific testing for DU among other types of radioactive material in flowback and in produced water and set standards and requirements for when radioactivity is found. Also IDNR should test for uranium238, radium226 and radium228 in flowback/produced water, drill cuttings, storage and reserve pit areas. Test for radium 226 and radium 228 in pipes and equipment, and radon222 at the wellhead.

Sincerely, Tybee McLaughlin Chicago, IL 60605

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Problem: The limited radioactivity testing requirement in this section does not adequately protect Illinois residents from the spread of dangerous radioactive materials. The statute and the proposed rule call for the testing of flowback (and not produced water) for "naturally occurring radioactive materials". However, the term "naturally occurring" is not defined in the statute or the proposed rules; DNR could interpret the quoted term so that testing will be required only for the specific radioactive materials that are expected to be found naturally in the subsurface at the well site. Depleted uranium would not be "naturally occurring" at the well site, so it will be undetected by the proposed testing. Depleted uranium (DU) is a highly dangerous radioactive material with a half-life of 4.5 billion years. It is a waste product left over when uranium is modified to produce fissionable material for nuclear reactors and weapons. We know that at least one of the major actors in the fracking industry has incorporated Depleted Uranium into its plan for perforating the gun assembly (for use in a wellbore) in horizontal fracturing operations. (See U.S. Patent No. 2011000069, "perforating gun assembly for use in a wellbore \*\*\* wherein the secondary pressure generator is selected from the group consisting of \*\*\* depleted uranium"; assignee of patent: Halliburton Energy Services, Inc.) Note that, in this case, radioactive material would be "added" radioactive material, not "naturally occurring." The General Assembly (implicitly) granted IDNR the authority to define "radioactivity." Radioactivity is a many splendored thing and comes in four major flavors: uranium 238, radium 226 and radium 228, and radon222. Each of these poses its own risks to our soil, water--and radon levels in our kitchens. So, will IDNR mandate testing for all four? Three? Two? One? The rule does not say. Revisions Needed: In order to protect the public health and safety and to preserve the health of our environment, DNR must require specific testing for DU among other types of radioactive material in flowback and in produced water and set standards and requirements for when radioactivity is found. Also IDNR should test for uranium238, radium226 and radium228 in flowback/produced water, drill cuttings, storage and reserve pit areas. Test for radium 226 and radium 228 in pipes and equipment, and radon222 at the wellhead.

Sincerely, Yijian Li Naperville, IL 60564

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Problem: The limited radioactivity testing requirement in this section does not adequately protect Illinois residents from the spread of dangerous radioactive materials. The statute and the proposed rule call for the testing of flowback (and not produced water) for "naturally occurring radioactive materials". However, the term "naturally occurring" is not defined in the statute or the proposed rules; DNR could interpret the quoted term so that testing will be required only for the specific radioactive materials that are expected to be found naturally in the subsurface at the well site. Depleted uranium would not be "naturally occurring" at the well site, so it will be undetected by the proposed testing. Depleted uranium (DU) is a highly dangerous radioactive material with a half-life of 4.5 billion years. It is a waste product left over when uranium is modified to produce fissionable material for nuclear reactors and weapons. We know that at least one of the major actors in the fracking industry has incorporated Depleted Uranium into its plan for perforating the gun assembly (for use in a wellbore) in horizontal fracturing operations. (See U.S. Patent No. 2011000069, "perforating gun assembly for use in a wellbore \*\*\* wherein the secondary pressure generator is selected from the group consisting of \*\*\* depleted uranium"; assignee of patent: Halliburton Energy Services, Inc.) Note that, in this case, radioactive material would be "added" radioactive material, not "naturally occurring." The General Assembly (implicitly) granted IDNR the authority to define "radioactivity." Radioactivity is a many splendored thing and comes in four major flavors: uranium 238, radium 226 and radium 228, and radon222. Each of these poses its own risks to our soil, water--and radon levels in our kitchens. So, will IDNR mandate testing for all four? Three? Two? One? The rule does not say. In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Problem: The proposed rules include no follow-up requirements or standards if testing shows radioactivity levels in flowback to be high. In other words, these proposed rules treat flowback the same whether it is highly radioactive or not! DNR knows that naturally occurring radioactivity material occurs in Illinois oil and gas operations. See 62 Ill. Admin. Code secs. 240.860(e)(3), 240.861(k)(1)(C). Revisions Needed: The rules must specify how flowback AND produced water will be treated if they test positive for radioactivity. The rules should also require that the requirements of the Illinois Low Level Radioactivity Waste Management Act be followed.

Sincerely, Adriana Caballero Oak Park, IL 60302

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Problem: The proposed rules include no follow-up requirements or standards if testing shows radioactivity levels in flowback to be high. In other words, these proposed rules treat flowback the same whether it is highly radioactive or not! DNR knows that naturally occurring radioactivity material occurs in Illinois oil and gas operations. See 62 Ill. Admin. Code secs. 240.860(e)(3), 240.861(k)(1)(C). The Act calls for a "traffic light" system seismicity. It is our opinion that such a traffic light system is far more important for radioactivity and IDNR has the "Power and authority" to create one. Yet, it does not do so. At what level is intervention by the Illinois Emergency Management Administration, which bears responsibility for the Low Level Radioactivity Management Act, appropriate under an interagency memorandum? IDNR does not say. At what level of worker exposure is OSHA involvement desirable? IDNR does not say. How is radioactive scrap pipe to be kept out of the recycle metal market? Once more, IDNR remains silent. Revisions Needed: The rules must specify how flowback AND produced water will be treated if they test positive for radioactivity. The rules should also require that the requirements of the Illinois Low Level Radioactivity Waste Management Act be followed. More specifically: 1. Test for uranium238, radium226 and radium228 in flowback/produced water, drill cuttings, storage and reserve pit areas. Test for radium 226 and radium 228 in pipes and equipment, and radon222 at the wellhead. 2. Rely on experts and scientific studies, to create a radioactivity traffic light system with cut points for: (1) controlled management, transportation, and disposal of any water, solids, or metals that meet or exceed criterion classifying it as low level radioactive waste; (2) guidance/intervention by OSHA when safety clothing, gloves and goggles are required to reduce workplace exposure; (3) quarantines for natural gas with elevated radon levels until those levels drop to a point where the gas is safe (after transport) for retail markets; (4) rigorous labeling, management, and disposal rules for radioactive pipe and equipment; (5) the posting of easily read, prominently displayed radioactive warning signs; (6) creating clean zones for eating and storing personal goods at wells sites deemed a potential workplace hazard.

Sincerely, Alex Farrenkopf Chicago, IL 60637

The rules should also require that the requirements of the Illinois Low Level Radioactivity Waste Management Act be followed. More specifically: 1. Test for uranium238, radium226 and radium228 in flowback/produced water, drill cuttings, storage and reserve pit areas. Test for radium 226 and radium 228 in pipes and equipment, and radon222 at the wellhead. 2. Rely on experts and scientific studies, to create a radioactivity traffic light system with cut points for: (1) controlled management, transportation, and disposal of any water, solids, or metals that meet or exceed criterion classifying it as low level radioactive waste; (2) guidance/intervention by OSHA when safety clothing, gloves and goggles are required to reduce workplace exposure; (3) quarantines for natural gas with elevated radon levels until those levels drop to a point where the gas is safe (after transport) for retail markets; (4) rigorous labeling, management, and disposal rules for radioactive pipe and equipment; (5) the posting of easily read, prominently displayed radioactive warning signs; (6) creating clean zones for eating and storing personal goods at wells sites deemed a potential workplace hazard.

Sincerely, Amelia Dmouska Chicago, IL 60637

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Problem: The proposed rules include no follow-up requirements or standards if testing shows radioactivity levels in flowback to be high. In other words, these proposed rules treat flowback the same whether it is highly radioactive or not! DNR knows that naturally occurring radioactivity material occurs in Illinois oil and gas operations. See 62 Ill. Admin. Code secs. 240.860(e)(3), 240.861(k)(1)(C). The Act calls for a "traffic light" system seismicity. It is our opinion that such a traffic light system is far more important for radioactivity and IDNR has the "Power and authority" to create one. Yet, it does not do so. At what level is intervention by the Illinois Emergency Management Administration, which bears responsibility for the Low Level Radioactivity Management Act, appropriate under an interagency memorandum? IDNR does not say. At what level of worker exposure is OSHA involvement desirable? IDNR does not say. How is radioactive scrap pipe to be kept out of the recycle metal market? Once more, IDNR remains silent. Revisions Needed: The rules must specify how flowback AND produced water will be treated if they test positive for radioactivity. The rules should also require that the requirements of the Illinois Low Level Radioactivity Waste Management Act be followed. More specifically: 1. Test for uranium238, radium226 and radium228 in flowback/produced water, drill cuttings, storage and reserve pit areas. Test for radium 226 and radium 228 in pipes and equipment, and radon222 at the wellhead. 2. At what level is intervention by the Illinois Emergency Management Administration, which bears responsibility for the Low Level Radioactivity Management Act, appropriate under an interagency memorandum? IDNR does not say. At what level of worker exposure is OSHA involvement desirable? IDNR does not say. How is radioactive scrap pipe to be kept out of the recycle metal market? Once more, IDNR remains silent. Revisions Needed: The rules must specify how flowback AND produced water will be treated if they test positive for radioactivity. The rules should also require that the requirements of the Illinois Low Level Radioactivity Waste Management Act be followed. More specifically: 1. Test for uranium238, radium226 and radium228 in flowback/produced water, drill cuttings, storage and reserve pit areas. Test for radium 226 and radium 228 in pipes and equipment, and radon222 at the wellhead. 2. Rely on experts and scientific studies, to create a radioactivity traffic light system with cut points for: (1) controlled management, transportation, and disposal of any water, solids, or metals that meet or exceed criterion classifying it as low level radioactive waste; (2) guidance/intervention by OSHA when safety clothing, gloves and goggles are required to reduce workplace exposure; (3) quarantines for natural gas with elevated radon levels until those levels drop to a point where the gas is safe (after transport) for retail markets; (4) rigorous labeling, management, and disposal rules for radioactive pipe and equipment; (5) the posting of easily read, prominently displayed radioactive warning signs; (6) creating clean zones for eating and storing personal goods at wells sites deemed a potential workplace hazard.

Sincerely, Ashley Seymour Chicago, IL 60615

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Problem: The proposed rules include no follow-up requirements or standards if testing shows radioactivity levels in flowback to be high. In other words, these proposed rules treat flowback the same whether it is highly radioactive or not! DNR knows that naturally occurring radioactivity material occurs in Illinois oil and gas operations. See 62 Ill. Admin. Code secs. 240.860(e)(3), 240.861(k)(1)(C). The Act calls for a "traffic light" system seismicity. It is our opinion that such a traffic light system is far more important for radioactivity and IDNR has the "Power and authority" to create one. Yet, it does not do so. At what level is intervention by the Illinois Emergency Management Administration, which bears responsibility for the Low Level Radioactivity Management Act, appropriate under an interagency memorandum? IDNR does not say. At what level of worker exposure is OSHA involvement desirable? IDNR does not say. How is radioactive scrap pipe to be kept out of the recycle metal market? Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Problem: The proposed rules include no follow-up requirements or standards if testing shows radioactivity levels in flowback to be high. In other words, these proposed rules treat flowback the same whether it is highly radioactive or not! DNR knows that naturally occurring radioactivity material occurs in Illinois oil and gas operations. See 62 Ill. Admin. Code secs. 240.860(e)(3), 240.861(k)(1)(C). The Act calls for a "traffic light" system seismicity. It is our opinion that such a traffic light system is far more important for radioactivity and IDNR has the "Power and authority" to create one. Yet, it does not do so. At what level is intervention by the Illinois Emergency Management Administration, which bears responsibility for the Low Level Radioactivity Management Act, appropriate under an interagency memorandum? IDNR does not say. At what level of worker exposure is OSHA involvement desirable? IDNR does not say. How is radioactive scrap pipe to be kept out of the recycle metal market? Once more, IDNR remains silent. Revisions Needed: The rules must specify how flowback AND produced water will be treated if they test positive for radioactivity. The rules should also require that the requirements of the Illinois Low Level Radioactivity Waste Management Act be followed. More specifically: 1. Test for uranium238, radium226 and radium228 in flowback/produced water, drill cuttings, storage and reserve pit areas. Test for radium 226 and radium 228 in pipes and equipment, and radon222 at the wellhead. 2. Rely on experts and scientific studies, to create a radioactivity traffic light system with cut points for: (1) controlled management, transportation, and disposal of any water, solids, or metals that meet or exceed criterion classifying it as low level radioactive waste; (2) guidance/intervention by OSHA when safety clothing, gloves and goggles are required to reduce workplace exposure; (3) quarantines for natural gas with elevated radon levels until those levels drop to a point where the gas is safe (after transport) for retail markets; (4) rigorous labeling, management, and disposal rules for radioactive pipe and equipment; (5) the posting of easily read, prominently displayed radioactive warning signs; (6) creating clean zones for eating and storing personal goods at wells sites deemed a potential workplace hazard.

Sincerely, Breanna Champion Chicago, IL 60616

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Problem: The proposed rules include no follow-up requirements or standards if testing shows radioactivity levels in flowback to be high. In other words, these proposed rules treat flowback the same whether it is highly radioactive or not! DNR knows that naturally occurring radioactivity material occurs in Illinois oil and gas operations. See 62 Ill. Admin. Code secs. 240.860(e)(3), 240.861(k)(1)(C). The Act calls for a "traffic light" system seismicity. It is our opinion that such a traffic light system is far more important for radioactivity and IDNR has the "Power and authority" to create one. Yet, it does not do so. At what level is intervention by the Illinois Emergency Management Administration, which bears responsibility for the Low Level Radioactivity Management Act, appropriate under an interagency memorandum? IDNR does not say. At what level of worker exposure is OSHA involvement desirable? IDNR does not say. How is radioactive scrap pipe to be kept out of the recycle metal market? Once more, IDNR remains silent. Revisions Needed: The rules must specify how flowback AND produced water will be treated if they test positive for radioactivity. The rules should also require that the requirements of the Illinois Low Level Radioactivity Waste Management Act be followed. More specifically: 1. Test for uranium238, radium226 and radium228 in flowback/produced water, drill cuttings, storage and reserve pit areas. Test for radium 226 and radium 228 in pipes and equipment, and radon222 at the wellhead. 2. Rely on experts and scientific studies, to create a radioactivity traffic light system with cut points for: (1) controlled management, transportation, and disposal of any water, solids, or metals that meet or exceed criterion classifying it as low level radioactive waste; (2) guidance/intervention by OSHA when safety clothing, gloves and goggles are required to reduce workplace exposure; (3) quarantines for natural gas with elevated radon levels until those levels drop to a point where the gas is safe (after transport) for retail markets; (4) rigorous labeling, management, and disposal rules for radioactive pipe and equipment; (5) the posting of easily read, prominently displayed radioactive warning signs; (6) creating clean zones for eating and storing personal goods at wells sites deemed a potential workplace hazard.

Sincerely, Clara Kao Chicago, IL 60637

IDNR does not say. At what level of worker exposure is OSHA involvement desirable? IDNR does not say. How is radioactive scrap pipe to be kept out of the recycle metal market? Once more, IDNR remains silent. Revisions Needed: The rules must specify how flowback AND produced water will be treated if they test positive for radioactivity. The rules should also require that the requirements of the Illinois Low Level Radioactivity Waste Management Act be followed. More specifically: 1. Test for uranium238, radium226 and radium228 in flowback/produced water, drill cuttings, storage and reserve pit areas. Test for radium 226 and radium 228 in pipes and equipment, and radon222 at the wellhead. 2. Rely on experts and scientific studies, to create a radioactivity traffic light system with cut points for: (1) controlled management, transportation, and disposal of any water, solids, or metals that meet or exceed criterion classifying it as low level radioactive waste; (2) guidance/intervention by OSHA when safety clothing, gloves and goggles are required to reduce workplace exposure; (3) quarantines for natural gas with elevated radon levels until those levels drop to a point where the gas is safe (after transport) for retail markets; (4) rigorous labeling, management, and disposal rules for radioactive pipe and equipment; (5) the posting of easily read, prominently displayed radioactive warning signs; (6) creating clean zones for eating and storing personal goods at wells sites deemed a potential workplace hazard.

Sincerely, Durango Mendoza Urbana, IL 61801

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Problem: The proposed rules include no follow-up requirements or standards if testing shows radioactivity levels in flowback to be high. In other words, these proposed rules treat flowback the same whether it is highly radioactive or not! DNR knows that naturally occurring radioactivity material occurs in Illinois oil and gas operations. See 62 Ill. Admin. Code secs. 240.860(e)(3), 240.861(k)(1)(C). The Act calls for a "traffic light" system seismicity. It is our opinion that such a traffic light system is far more important for radioactivity and IDNR has the "Power and authority" to create one. Yet, it does not do so. At what level is intervention by the Illinois Emergency Management Administration, which bears responsibility for the Low Level Radioactivity Management Act, appropriate under an interagency memorandum? IDNR does not say. At what level of worker exposure is OSHA involvement desirable? IDNR does not say. How is radioactive scrap pipe to be kept out of the recycle metal market? Once more, IDNR remains silent. Revisions Needed: The rules must specify how flowback AND produced water will be treated if they test positive for radioactivity. The rules should also require that the requirements of the Illinois Low Level Radioactivity Waste Management Act be followed. More specifically: 1. At what level is intervention by the Illinois Emergency Management Administration, which bears responsibility for the Low Level Radioactivity Management Act, appropriate under an interagency memorandum? IDNR does not say. At what level of worker exposure is OSHA involvement desirable? IDNR does not say. How is radioactive scrap pipe to be kept out of the recycle metal market? Once more, IDNR remains silent. Revisions Needed: The rules must specify how flowback AND produced water will be treated if they test positive for radioactivity. The rules should also require that the requirements of the Illinois Low Level Radioactivity Waste Management Act be followed. More specifically: 1. Test for uranium238, radium226 and radium228 in flowback/produced water, drill cuttings, storage and reserve pit areas. Test for radium 226 and radium 228 in pipes and equipment, and radon222 at the wellhead. 2. Rely on experts and scientific studies, to create a radioactivity traffic light system with cut points for: (1) controlled management, transportation, and disposal of any water, solids, or metals that meet or exceed criterion classifying it as low level radioactive waste; (2) guidance/intervention by OSHA when safety clothing, gloves and goggles are required to reduce workplace exposure; (3) quarantines for natural gas with elevated radon levels until those levels drop to a point where the gas is safe (after transport) for retail markets; (4) rigorous labeling, management, and disposal rules for radioactive pipe and equipment; (5) the posting of easily read, prominently displayed radioactive warning signs; (6) creating clean zones for eating and storing personal goods at wells sites deemed a potential workplace hazard.

Sincerely, Emily Huang Chicago, IL 60637

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Problem: The proposed rules include no follow-up requirements or standards if testing shows radioactivity levels in flowback to be high. In other words, these proposed rules treat flowback the same whether it is highly radioactive or not! DNR knows that naturally occurring radioactivity material occurs in Illinois oil and gas operations. See 62 Ill. Admin. Code secs. 240.860(e)(3), 240.861(k)(1)(C). Revisions Needed: The rules must specify how flowback AND produced water will be treated if they test positive for radioactivity. The rules should also require that the requirements of the Illinois Low Level Radioactivity Waste Management Act be followed.

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Problem: The proposed rules include no follow-up requirements or standards if testing shows radioactivity levels in flowback to be high. In other words, these proposed rules treat flowback the same whether it is highly radioactive or not! DNR knows that naturally occurring radioactivity material occurs in Illinois oil and gas operations. See 62 Ill. Admin. Code secs. 240.860(e)(3), 240.861(k)(1)(C). The Act calls for a "traffic light" system seismicity. It is our opinion that such a traffic light system is far more important for radioactivity and IDNR has the "Power and authority" to create one. Yet, it does not do so. At what level is intervention by the Illinois Emergency Management Administration, which bears responsibility for the Low Level Radioactivity Management Act, appropriate under an interagency memorandum? IDNR does not say. At what level of worker exposure is OSHA involvement desirable? IDNR does not say. How is radioactive scrap pipe to be kept out of the recycle metal market? Once more, IDNR remains silent. Revisions Needed: The rules must specify how flowback AND produced water will be treated if they test positive for radioactivity. The rules should also require that the requirements of the Illinois Low Level Radioactivity Waste Management Act be followed. More specifically: 1. Test for uranium238, radium226 and radium228 in flowback/produced water, drill cuttings, storage and reserve pit areas. Test for radium 226 and radium 228 in pipes and equipment, and radon222 at the wellhead. 2. Rely on experts and scientific studies, to create a radioactivity traffic light system with cut points for: (1) controlled management, transportation, and disposal of any water, solids, or metals that meet or exceed criterion classifying it as low level radioactive waste; (2) guidance/intervention by OSHA when safety clothing, gloves and goggles are required to reduce workplace exposure; (3) quarantines for natural gas with elevated radon levels until those levels drop to a point where the gas is safe (after transport) for retail markets; (4) rigorous labeling, management, and disposal rules for radioactive pipe and equipment; (5) the posting of easily read, prominently displayed radioactive warning signs; (6) creating clean zones for eating and storing personal goods at wells sites deemed a potential workplace hazard.

Sincerely, Jady YTolda chicago, IL 60637

DNR knows that naturally occurring radioactivity material occurs in Illinois oil and gas operations. See 62 Ill. Admin. Code secs. 240.860(e)(3), 240.861(k)(1)(C). The Act calls for a "traffic light" system seismicity. It is our opinion that such a traffic light system is far more important for radioactivity and IDNR has the "Power and authority" to create one. Yet, it does not do so. At what level is intervention by the Illinois Emergency Management Administration, which bears responsibility for the Low Level Radioactivity Management Act, appropriate under an interagency memorandum? IDNR does not say. At what level of worker exposure is OSHA involvement desirable? IDNR does not say. How is radioactive scrap pipe to be kept out of the recycle metal market? Once more, IDNR remains silent. Revisions Needed: The rules must specify how flowback AND produced water will be treated if they test positive for radioactivity. The rules should also require that the requirements of the Illinois Low Level Radioactivity Waste Management Act be followed. More specifically: 1. Test for uranium238, radium226 and radium228 in flowback/produced water, drill cuttings, storage and reserve pit areas. Test for radium 226 and radium 228 in pipes and equipment, and radon222 at the wellhead. 2. Rely on experts and scientific studies, to create a radioactivity traffic light system with cut points for: (1) controlled management, transportation, and disposal of any water, solids, or metals that meet or exceed criterion classifying it as low level radioactive waste; (2) guidance/intervention by OSHA when safety clothing, gloves and goggles are required to reduce workplace exposure; (3) quarantines for natural gas with elevated radon levels until those levels drop to a point where the gas is safe (after transport) for retail markets; (4) rigorous labeling, management, and disposal rules for radioactive pipe and equipment; (5) the posting of easily read, prominently displayed radioactive warning signs; (6) creating clean zones for eating and storing personal goods at wells sites deemed a potential workplace hazard.

Sincerely, Joey Knotts Chicago, IL 60605

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Problem: The proposed rules include no follow-up requirements or standards if testing shows radioactivity levels in flowback to be high. In other words, these proposed rules treat flowback the same whether it is highly radioactive or not! DNR knows that naturally occurring radioactivity material occurs in Illinois oil and gas operations. See 62 Ill. Admin. Code secs. 240.860(e)(3), 240.861(k)(1)(C). Revisions Needed: The rules must specify how flowback AND produced water will be treated if they test positive for radioactivity. The rules should also require that the requirements of the Illinois Low Level Radioactivity Waste Management Act be followed.

Sincerely, Johnathan Guy Burton Judson Hall, 1005 E 60th St Chicago, IL 60637

Test for uranium238, radium226 and radium228 in flowback/produced water, drill cuttings, storage and reserve pit areas. Test for radium 226 and radium 228 in pipes and equipment, and radon222 at the wellhead. 2. Rely on experts and scientific studies, to create a radioactivity traffic light system with cut points for: (1) controlled management, transportation, and disposal of any water, solids, or metals that meet or exceed criterion classifying it as low level radioactive waste; (2) guidance/intervention by OSHA when safety clothing, gloves and goggles are required to reduce workplace exposure; (3) quarantines for natural gas with elevated radon levels until those levels drop to a point where the gas is safe (after transport) for retail markets; (4) rigorous labeling, management, and disposal rules for radioactive pipe and equipment; (5) the posting of easily read, prominently displayed radioactive warning signs; (6) creating clean zones for eating and storing personal goods at wells sites deemed a potential workplace hazard.

Sincerely, Katie Lettie Chicago, IL 60637

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Problem: The proposed rules include no follow-up requirements or standards if testing shows radioactivity levels in flowback to be high. In other words, these proposed rules treat flowback the same whether it is highly radioactive or not! DNR knows that naturally occurring radioactivity material occurs in Illinois oil and gas operations. See 62 Ill. Admin. Code secs. 240.860(e)(3), 240.861(k)(1)(C). The Act calls for a "traffic light" system seismicity. It is our opinion that such a traffic light system is far more important for radioactivity and IDNR has the "Power and authority" to create one. Yet, it does not do so. At what level is intervention by the Illinois Emergency Management Administration, which bears responsibility for the Low Level Radioactivity Management Act, appropriate under an interagency memorandum? IDNR does not say. At what level of worker exposure is OSHA involvement desirable? IDNR does not say. How is radioactive scrap pipe to be kept out of the recycle metal market? Once more, IDNR remains silent. Revisions Needed: The rules must specify how flowback AND produced water will be treated if they test positive for radioactivity. The rules should also require that the requirements of the Illinois Low Level Radioactivity Waste Management Act be followed. More specifically: 1. Test for uranium238, radium226 and radium228 in flowback/produced water, drill cuttings, storage and reserve pit areas. Test for radium 226 and radium 228 in pipes and equipment, and radon222 at the wellhead. 2. Rely on experts and scientific studies, to create a radioactivity traffic light system with cut points for: (1) controlled management, transportation, and disposal of any water, solids, or metals that meet or exceed criterion classifying it as low level radioactive waste; (2) guidance/intervention by OSHA when safety clothing, gloves and goggles are required to reduce workplace exposure; (3) quarantines for natural gas with elevated radon levels until those levels drop to a point where the gas is safe (after transport) for retail markets; (4) rigorous labeling, management, and disposal rules for radioactive pipe and equipment; (5) the posting of easily read, prominently displayed radioactive warning signs; (6) creating clean zones for eating and storing personal goods at wells sites deemed a potential workplace hazard.

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Problem: The proposed rules include no follow-up requirements or standards if testing shows radioactivity levels in flowback to be high. In other words, these proposed rules treat flowback the same whether it is highly radioactive or not! DNR knows that naturally occurring radioactivity material occurs in Illinois oil and gas operations. See 62 Ill. Admin. Code secs. 240.860(e)(3), 240.861(k)(1)(C). The Act calls for a "traffic light" system seismicity. It is our opinion that such a traffic light system is far more important for radioactivity and IDNR has the "Power and authority" to create one. Yet, it does not do so. At what level is intervention by the Illinois Emergency Management Administration, which bears responsibility for the Low Level Radioactivity Management Act, appropriate under an interagency memorandum? IDNR does not say. At what level of worker exposure is OSHA involvement desirable? IDNR does not say. How is radioactive scrap pipe to be kept out of the recycle metal market? Once more, IDNR remains silent. Revisions Needed: The rules must specify how flowback AND produced water will be treated if they test positive for radioactivity. The rules should also require that the requirements of the Illinois Low Level Radioactivity Waste Management Act be followed. More specifically: 1. Test for uranium238, radium226 and radium228 in flowback/produced water, drill cuttings, storage and reserve pit areas. Test for radium 226 and radium 228 in pipes and equipment, and radon222 at the wellhead. 2. Rely on experts and scientific studies, to create a radioactivity traffic light system with cut points for: (1) controlled management, transportation, and disposal of any water, solids, or metals that meet or exceed criterion classifying it as low level radioactive waste; (2) guidance/intervention by OSHA when safety clothing, gloves and goggles are required to reduce workplace exposure; (3) quarantines for natural gas with elevated radon levels until those levels drop to a point where the gas is safe (after transport) for retail markets; (4) rigorous labeling, management, and disposal rules for radioactive pipe and equipment; (5) the posting of easily read, prominently displayed radioactive warning signs; (6) creating clean zones for eating and storing personal goods at wells sites deemed a potential workplace hazard.

Sincerely, Liza Pono Chicago, IL 60616

Test for radium 226 and radium 228 in pipes and equipment, and radon222 at the wellhead. 2. Rely on experts and scientific studies, to create a radioactivity traffic light system with cut points for: (1) controlled management, transportation, and disposal of any water, solids, or metals that meet or exceed criterion classifying it as low level radioactive waste; (2) guidance/intervention by OSHA when safety clothing, gloves and goggles are required to reduce workplace exposure; (3) quarantines for natural gas with elevated radon levels until those levels drop to a point where the gas is safe (after transport) for retail markets; (4) rigorous labeling, management, and disposal rules for radioactive pipe and equipment; (5) the posting of easily read, prominently displayed radioactive warning signs; (6) creating clean zones for eating and storing personal goods at wells sites deemed a potential workplace hazard.

Sincerely, Min Li Naperville, IL 60564

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Problem: The proposed rules include no follow-up requirements or standards if testing shows radioactivity levels in flowback to be high. In other words, these proposed rules treat flowback the same whether it is highly radioactive or not! DNR knows that naturally occurring radioactivity material occurs in Illinois oil and gas operations. See 62 Ill. Admin. Code secs. 240.860(e)(3), 240.861(k)(1)(C). The Act calls for a "traffic light" system seismicity. It is our opinion that such a traffic light system is far more important for radioactivity and IDNR has the "Power and authority" to create one. Yet, it does not do so. At what level is intervention by the Illinois Emergency Management Administration, which bears responsibility for the Low Level Radioactivity Management Act, appropriate under an interagency memorandum? IDNR does not say. At what level of worker exposure is OSHA involvement desirable? IDNR does not say. How is radioactive scrap pipe to be kept out of the recycle metal market? Once more, IDNR remains silent. Revisions Needed: The rules must specify how flowback AND produced water will be treated if they test positive for radioactivity. The rules should also require that the requirements of the Illinois Low Level Radioactivity Waste Management Act be followed. More specifically: 1. Test for uranium238, radium226 and radium228 in flowback/produced water, drill cuttings, storage and reserve pit areas. Test for radium 226 and radium 228 in pipes and equipment, and radon222 at the wellhead. 2. Rely on experts and scientific studies, to create a radioactivity traffic light system with cut points for: (1) controlled management, transportation, and disposal of any water, solids, or metals that meet or exceed criterion classifying it as low level radioactive waste; (2) guidance/intervention by OSHA when safety clothing, gloves and goggles are required to reduce workplace exposure; (3) quarantines for natural gas with elevated radon levels until those levels drop to a point where the gas is safe (after transport) for retail markets; (4) rigorous labeling, management, and disposal rules for radioactive pipe and equipment; (5) the posting of easily read, prominently displayed radioactive warning signs; (6) creating clean zones for eating and storing personal goods at wells sites deemed a potential workplace hazard.

In other words, these proposed rules treat flowback the same whether it is highly radioactive or not! DNR knows that naturally occurring radioactivity material occurs in Illinois oil and gas operations. See 62 Ill. Admin. Code secs. 240.860(e)(3), 240.861(k)(1)(C). The Act calls for a "traffic light" system seismicity. It is our opinion that such a traffic light system is far more important for radioactivity and IDNR has the "Power and authority" to create one. Yet, it does not do so. At what level is intervention by the Illinois Emergency Management Administration, which bears responsibility for the Low Level Radioactivity Management Act, appropriate under an interagency memorandum? IDNR does not say. At what level of worker exposure is OSHA involvement desirable? IDNR does not say. How is radioactive scrap pipe to be kept out of the recycle metal market? Once more, IDNR remains silent. Revisions Needed: The rules must specify how flowback AND produced water will be treated if they test positive for radioactivity. The rules should also require that the requirements of the Illinois Low Level Radioactivity Waste Management Act be followed. More specifically: 1. Test for uranium238, radium226 and radium228 in flowback/produced water, drill cuttings, storage and reserve pit areas. Test for radium 226 and radium 228 in pipes and equipment, and radon222 at the wellhead. 2. Rely on experts and scientific studies, to create a radioactivity traffic light system with cut points for: (1) controlled management, transportation, and disposal of any water, solids, or metals that meet or exceed criterion classifying it as low level radioactive waste; (2) guidance/intervention by OSHA when safety clothing, gloves and goggles are required to reduce workplace exposure; (3) quarantines for natural gas with elevated radon levels until those levels drop to a point where the gas is safe (after transport) for retail markets; (4) rigorous labeling, management, and disposal rules for radioactive pipe and equipment; (5) the posting of easily read, prominently displayed radioactive warning signs; (6) creating clean zones for eating and storing personal goods at wells sites deemed a potential workplace hazard.

Sincerely, Paloma Delgadillo Plano, IL 75075

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Problem: The proposed rules include no follow-up requirements or standards if testing shows radioactivity levels in flowback to be high. In other words, these proposed rules treat flowback the same whether it is highly radioactive or not! DNR knows that naturally occurring radioactivity material occurs in Illinois oil and gas operations. See 62 Ill. Admin. Code secs. 240.860(e)(3), 240.861(k)(1)(C). Revisions Needed: The rules must specify how flowback AND produced water will be treated if they test positive for radioactivity. The Act calls for a "traffic light" system seismicity. It is our opinion that such a traffic light system is far more important for radioactivity and IDNR has the "Power and authority" to create one. Yet, it does not do so. At what level is intervention by the Illinois Emergency Management Administration, which bears responsibility for the Low Level Radioactivity Management Act, appropriate under an interagency memorandum? IDNR does not say. At what level of worker exposure is OSHA involvement desirable? IDNR does not say. How is radioactive scrap pipe to be kept out of the recycle metal market? Once more, IDNR remains silent. Revisions Needed: The rules must specify how flowback AND produced water will be treated if they test positive for radioactivity. The rules should also require that the requirements of the Illinois Low Level Radioactivity Waste Management Act be followed. More specifically: 1. Test for uranium238, radium226 and radium228 in flowback/produced water, drill cuttings, storage and reserve pit areas. Test for radium 226 and radium 228 in pipes and equipment, and radon222 at the wellhead. 2. Rely on experts and scientific studies, to create a radioactivity traffic light system with cut points for: (1) controlled management, transportation, and disposal of any water, solids, or metals that meet or exceed criterion classifying it as low level radioactive waste; (2) guidance/intervention by OSHA when safety clothing, gloves and goggles are required to reduce workplace exposure; (3) quarantines for natural gas with elevated radon levels until those levels drop to a point where the gas is safe (after transport) for retail markets; (4) rigorous labeling, management, and disposal rules for radioactive pipe and equipment; (5) the posting of easily read, prominently displayed radioactive warning signs; (6) creating clean zones for eating and storing personal goods at wells sites deemed a potential workplace hazard.

Sincerely, Rebekah Sugarman Syosset, IL 11791

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Problem: The proposed rules include no follow-up requirements or standards if testing shows radioactivity levels in flowback to be high. In other words, these proposed rules treat flowback the same whether it is highly radioactive or not! DNR knows that naturally occurring radioactivity material occurs in Illinois oil and gas operations. See 62 Ill. Admin. Code secs. 240.860(e)(3), 240.861(k)(1)(C). The Act calls for a "traffic light" system seismicity. It is our opinion that such a traffic light system is far more important for radioactivity and IDNR has the "Power and authority" to create one. Yet, it does not do so. At what level is intervention by the Illinois Emergency Management Administration, which bears responsibility for the Low Level Radioactivity Management Act, appropriate under an interagency memorandum? DNR knows that naturally occurring radioactivity material occurs in Illinois oil and gas operations. See 62 Ill. Admin. Code secs. 240.860(e)(3), 240.861(k)(1)(C). The Act calls for a "traffic light" system seismicity. It is our opinion that such a traffic light system is far more important for radioactivity and IDNR has the "Power and authority" to create one. Yet, it does not do so. At what level is intervention by the Illinois Emergency Management Administration, which bears responsibility for the Low Level Radioactivity Management Act, appropriate under an interagency memorandum? IDNR does not say. At what level of worker exposure is OSHA involvement desirable? IDNR does not say. How is radioactive scrap pipe to be kept out of the recycle metal market? Once more, IDNR remains silent. Revisions Needed: The rules must specify how flowback AND produced water will be treated if they test positive for radioactivity. The rules should also require that the requirements of the Illinois Low Level Radioactivity Waste Management Act be followed. More specifically: 1. Test for uranium238, radium226 and radium228 in flowback/produced water, drill cuttings, storage and reserve pit areas. Test for radium 226 and radium 228 in pipes and equipment, and radon222 at the wellhead. 2. Rely on experts and scientific studies, to create a radioactivity traffic light system with cut points for: (1) controlled management, transportation, and disposal of any water, solids, or metals that meet or exceed criterion classifying it as low level radioactive waste; (2) guidance/intervention by OSHA when safety clothing, gloves and goggles are required to reduce workplace exposure; (3) quarantines for natural gas with elevated radon levels until those levels drop to a point where the gas is safe (after transport) for retail markets; (4) rigorous labeling, management, and disposal rules for radioactive pipe and equipment; (5) the posting of easily read, prominently displayed radioactive warning signs; (6) creating clean zones for eating and storing personal goods at wells sites deemed a potential workplace hazard.

Sincerely, Rui Chicago, IL 60637

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Problem: The proposed rules include no follow-up requirements or standards if testing shows radioactivity levels in flowback to be high. In other words, these proposed rules treat flowback the same whether it is highly radioactive or not! DNR knows that naturally occurring radioactivity material occurs in Illinois oil and gas operations. See 62 Ill. Admin. Code secs. 240.860(e)(3), 240.861(k)(1)(C). The Act calls for a "traffic light" system seismicity. It is our opinion that such a traffic light system is far more important for radioactivity and IDNR has the "Power and authority" to create one. Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Problem: The proposed rules include no follow-up requirements or standards if testing shows radioactivity levels in flowback to be high. In other words, these proposed rules treat flowback the same whether it is highly radioactive or not! DNR knows that naturally occurring radioactivity material occurs in Illinois oil and gas operations. See 62 Ill. Admin. Code secs. 240.860(e)(3), 240.861(k)(1)(C). The Act calls for a "traffic light" system seismicity. It is our opinion that such a traffic light system is far more important for radioactivity and IDNR has the "Power and authority" to create one. Yet, it does not do so. At what level is intervention by the Illinois Emergency Management Administration, which bears responsibility for the Low Level Radioactivity Management Act, appropriate under an interagency memorandum? IDNR does not say. At what level of worker exposure is OSHA involvement desirable? IDNR does not say. How is radioactive scrap pipe to be kept out of the recycle metal market? Once more, IDNR remains silent. Revisions Needed: The rules must specify how flowback AND produced water will be treated if they test positive for radioactivity. The rules should also require that the requirements of the Illinois Low Level Radioactivity Waste Management Act be followed. More specifically: 1. Test for uranium238, radium226 and radium228 in flowback/produced water, drill cuttings, storage and reserve pit areas. Test for radium 226 and radium 228 in pipes and equipment, and radon222 at the wellhead. 2. Rely on experts and scientific studies, to create a radioactivity traffic light system with cut points for: (1) controlled management, transportation, and disposal of any water, solids, or metals that meet or exceed criterion classifying it as low level radioactive waste; (2) guidance/intervention by OSHA when safety clothing, gloves and goggles are required to reduce workplace exposure; (3) quarantines for natural gas with elevated radon levels until those levels drop to a point where the gas is safe (after transport) for retail markets; (4) rigorous labeling, management, and disposal rules for radioactive pipe and equipment; (5) the posting of easily read, prominently displayed radioactive warning signs; (6) creating clean zones for eating and storing personal goods at wells sites deemed a potential workplace hazard.

Sincerely, Sean Tyler Chicago, IL 60605

The Act calls for a "traffic light" system seismicity. It is our opinion that such a traffic light system is far more important for radioactivity and IDNR has the "Power and authority" to create one. Yet, it does not do so. At what level is intervention by the Illinois Emergency Management Administration, which bears responsibility for the Low Level Radioactivity Management Act, appropriate under an interagency memorandum? IDNR does not say. At what level of worker exposure is OSHA involvement desirable? IDNR does not say. How is radioactive scrap pipe to be kept out of the recycle metal market? Once more, IDNR remains silent. Revisions Needed: The rules must specify how flowback AND produced water will be treated if they test positive for radioactivity. The rules should also require that the requirements of the Illinois Low Level Radioactivity Waste Management Act be followed. More specifically: 1. Test for uranium 238, radium 226 and radium 228 in flowback/produced water, drill cuttings, storage and reserve pit areas. Test for radium 226 and radium 228 in pipes and equipment, and radon 222 at the wellhead. 2. Rely on experts and scientific studies, to create a radioactivity traffic light system with cut points for: (1) controlled management, transportation, and disposal of any water, solids, or metals that meet or exceed criterion classifying it as low level radioactive waste; (2) guidance/intervention by OSHA when safety clothing, gloves and goggles are required to reduce workplace exposure; (3) quarantines for natural gas with elevated radon levels until those levels drop to a point where the gas is safe (after transport) for retail markets; (4) rigorous labeling, management, and disposal rules for radioactive pipe and equipment; (5) the posting of easily read, prominently displayed radioactive warning signs; (6) creating clean zones for eating and storing personal goods at wells sites deemed a potential workplace hazard.

Sincerely, Sophia Johnson Chicago, IL 60605

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Problem: The proposed rules include no follow-up requirements or standards if testing shows radioactivity levels in flowback to be high. In other words, these proposed rules treat flowback the same whether it is highly radioactive or not! DNR knows that naturally occurring radioactivity material occurs in Illinois oil and gas operations. See 62 Ill. Admin. Code secs. 240.860(e)(3), 240.861(k)(1)(C). The Act calls for a "traffic light" system seismicity. It is our opinion that such a traffic light system is far more important for radioactivity and IDNR has the "Power and authority" to create one. Yet, it does not do so. At what level is intervention by the Illinois Emergency Management Administration, which bears responsibility for the Low Level Radioactivity Management Act, appropriate under an interagency memorandum? In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Problem: The proposed rules include no follow-up requirements or standards if testing shows radioactivity levels in flowback to be high. In other words, these proposed rules treat flowback the same whether it is highly radioactive or not! DNR knows that naturally occurring radioactivity material occurs in Illinois oil and gas operations. See 62 Ill. Admin. Code secs. 240.860(e)(3), 240.861(k)(1)(C). The Act calls for a "traffic light" system seismicity. It is our opinion that such a traffic light system is far more important for radioactivity and IDNR has the "Power and authority" to create one. Yet, it does not do so. At what level is intervention by the Illinois Emergency Management Administration, which bears responsibility for the Low Level Radioactivity Management Act, appropriate under an interagency memorandum? IDNR does not say. At what level of worker exposure is OSHA involvement desirable? IDNR does not say. How is radioactive scrap pipe to be kept out of the recycle metal market? Once more, IDNR remains silent. Revisions Needed: The rules must specify how flowback AND produced water will be treated if they test positive for radioactivity. The rules should also require that the requirements of the Illinois Low Level Radioactivity Waste Management Act be followed. More specifically: 1. Test for uranium238, radium226 and radium228 in flowback/produced water, drill cuttings, storage and reserve pit areas. Test for radium 226 and radium 228 in pipes and equipment, and radon222 at the wellhead. 2. Rely on experts and scientific studies, to create a radioactivity traffic light system with cut points for: (1) controlled management, transportation, and disposal of any water, solids, or metals that meet or exceed criterion classifying it as low level radioactive waste; (2) guidance/intervention by OSHA when safety clothing, gloves and goggles are required to reduce workplace exposure; (3) quarantines for natural gas with elevated radon levels until those levels drop to a point where the gas is safe (after transport) for retail markets; (4) rigorous labeling, management, and disposal rules for radioactive pipe and equipment; (5) the posting of easily read, prominently displayed radioactive warning signs; (6) creating clean zones for eating and storing personal goods at wells sites deemed a potential workplace hazard.

Sincerely, Weili Zheng Chicago, IL 60607

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Problem: The proposed rules include no follow-up requirements or standards if testing shows radioactivity levels in flowback to be high. In other words, these proposed rules treat flowback the same whether it is highly radioactive or not! DNR knows that naturally occurring radioactivity material occurs in Illinois oil and gas operations. See 62 Ill. Admin. Code secs. 240.860(e)(3), 240.861(k)(1)(C). The Act calls for a "traffic light" system seismicity. It is our opinion that such a traffic light system is far more important for radioactivity and IDNR has the "Power and authority" to create one. Yet, it does not do so. At what level is intervention by the Illinois Emergency Management Administration, which bears responsibility for the Low Level Radioactivity Management Act, appropriate under an interagency memorandum? IDNR does not say. At what level of worker exposure is OSHA involvement desirable? IDNR does not say. How is radioactive scrap pipe to be kept out of the recycle metal market? Once more, IDNR remains silent. Revisions Needed: The rules must specify how flowback AND produced water will be treated if they test positive for radioactivity. The rules should also require that the requirements of the Illinois Low Level Radioactivity Waste Management Act be followed. More specifically: 1. Test for uranium238, radium226 and radium228 in flowback/produced water, drill cuttings, storage and reserve pit areas. Test for radium 226 and radium 228 in pipes and equipment, and radon222 at the wellhead. 2. Rely on experts and scientific studies, to create a radioactivity traffic light system with cut points for: (1) controlled management, transportation, and disposal of any water, solids, or metals that meet or exceed criterion classifying it as low level radioactive waste; (2) guidance/intervention by OSHA when safety clothing, gloves and goggles are required to reduce workplace exposure; (3) quarantines for natural gas with elevated radon levels until those levels drop to a point where the gas is safe (after transport) for retail markets; (4) rigorous labeling, management, and disposal rules for radioactive pipe and equipment; (5) the posting of easily read, prominently displayed radioactive warning signs; (6) creating clean zones for eating and storing personal goods at wells sites deemed a potential workplace hazard.

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Subsection (d)(1) of Section 245.850 provides for testing of fracking fluids only one time--during the early flowback stage--and only for "naturally occurring radioactive materials." Problem: The limited radioactivity testing requirement in this section does not adequately protect Illinois residents from the spread of dangerous radioactive materials. The statute and the proposed rule call for the testing of flowback (and not produced water) for "naturally occurring radioactive materials". However, the term "naturally occurring" is not defined in the statute or the proposed rules; DNR could interpret the quoted term so that testing will be required only for the specific radioactive materials that are expected to be found naturally in the subsurface at the well site. Depleted uranium would not be "naturally occurring" at the well site, so it will be undetected by the proposed testing. Depleted uranium (DU) is a highly dangerous radioactive material with a half-life of 4.5 billion years. It is a waste product left over when uranium is modified to produce fissionable material for nuclear reactors and weapons. We know that at least one of the major actors in the fracking industry has incorporated Depleted Uranium into its plan for perforating the gun assembly (for use in a wellbore) in horizontal fracturing operations. (See U.S. Patent No. 2011000069, "perforating gun assembly for use in a wellbore \*\*\* wherein the secondary pressure generator is selected from the group consisting of \*\*\* depleted uranium"; assignee of patent: Halliburton Energy Services, Inc.) Note that, in this case, radioactive material would be "added" radioactive material, not "naturally occurring." Revisions Needed: In order to protect the public health and safety and to preserve the health of our environment, DNR must require specific testing for DU among other types of radioactive material in flowback and in produced water and set standards and requirements for when radioactivity is found. I am SOOOOOOOO tired of companies getting away with these practices and polluting our land and our water!! We must stop investing in a system that makes earth, and the humans who inhabit it, sick!!

Sincerely, Keri Curtis Peru, IL 61354

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Subsection (d)(1) of Section 245.850 provides for testing radioactivity only one time— during the early flowback stage—and only for "naturally occurring radioactive materials". The problems with this are identified below. I would like to see the following changes: -The rules must include any standards or protocols to follow if testing of flowback water shows unacceptable levels of radioactivity. -The rules must require the testing of "produced water", which is the water produced from a well in conjunction with oil or natural gas production. This is where radioactivity is most likely to show up. -The rules must require testing for added radioactive materials, like depleted uranium, which can be used in the perforation/fracturing operation. -The rules must test work areas for levels of radioactivity that would call for OSHA standards of occupational safety. Without the above specifications, cumulatively or singly, the proposed rules would allow significant risk to the public health and safety, property, aquatic life, and wildlife, in violation of section 1-75(a)(2) of the Hydraulic Fracturing Regulatory Act.

Sincerely, Amanda Woodall 4949 N. Whipple Street Chicago, IL 60625

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Subsection (d)(1) of Section 245.850 provides for testing radioactivity only one time— during the early flowback stage—and only for "naturally occurring radioactive materials". The problems with this are identified below. It would probably be helpful to know about the non-naturally occurring radioactive materials level as well. The rules don't even comply with OSHA standards of safety. When I worked in my universities office of environmental health and safety, EVERYTHING had to follow OSHA standards. Even electrophoresis gels ordered for freshman level science labs that do not even have that much known radioactivity. When you sell your house, you have to test it for radon if needed. These rules need to be mores stringent.

Sincerely, Harry Li 2656 Boddington Lane Naperville, IL 60564

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Subsection (d)(1) of Section 245.850 provides for testing radioactivity only one time— during the early flowback stage—and only for "naturally occurring radioactive materials". The problems with this are identified below. Problems: The proposed rules do not include any standards or protocols to follow if testing of flowback water shows unacceptable levels of radioactivity. The proposed rules do not require the testing of "produced water", which is the water produced from a well in conjunction with oil or natural gas production. This is where radioactivity is most likely to show up. It should be noted that while these Rules have been purported to be the strongest in the nation, PA law requires the testing of produced water at two separate intervals. The proposed rules do not require testing for added radioactive materials, like depleted uranium, which can be used in the perforation/fracturing operation. The proposed rules do not test work areas for levels of radioactivity that would call for OSHA standards of occupational safety. Rules §245.850(d)1-E and §245.850(e) are incomplete and deficient, and these inadequacies can "constitute a serious threat"--indeed, deadly threat-- "to the public interest, safety, or welfare" of Illinois citizens" and are in violation of section 1-75(a)(2) of the Hydraulic Fracturing Regulatory Act.

Sincerely, Alonzo Cummins Chicago, IL 60612

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Subsection (d)(1) of Section 245.850 provides for testing radioactivity only one time— during the early flowback stage—and only for "naturally occurring radioactive materials". The problems with this are identified below. Problems: The proposed rules do not include any standards or protocols to follow if testing of flowback water shows unacceptable levels of radioactivity. The proposed rules do not require the testing of "produced water", which is the water produced from a well in conjunction with oil or natural gas production. This is where radioactivity is most likely to show up. It should be noted that while these Rules have been purported to be the strongest in the nation, PA law requires the testing of produced water at two separate intervals. The proposed rules do not require testing for added radioactive materials, like depleted uranium, which can be used in the perforation/fracturing operation. The proposed rules do not test work areas for levels of radioactivity that would call for OSHA standards of occupational safety. Rules §245.850(d)1-E and §245.850(e) are incomplete and deficient, and these inadequacies can "constitute a serious threat"--indeed, deadly threat-- "to the public interest, safety, or welfare" of Illinois citizens" and are in violation of section 1-75(a)(2) of the Hydraulic Fracturing Regulatory Act.

Sincerely, Benjamin Boyajian Chicago, IL 60615

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Subsection (d)(1) of Section 245.850 provides for testing radioactivity only one time— during the early flowback stage—and only for "naturally occurring radioactive materials". The problems with this are identified below. Problems: The proposed rules do not include any standards or protocols to follow if testing of flowback water shows unacceptable levels of radioactivity. The proposed rules do not require the testing of "produced water", which is the water produced from a well in conjunction with oil or natural gas production. This is where radioactivity is most likely to show up. It should be noted that while these Rules have been purported to be the strongest in the nation, PA law requires the testing of produced water at two separate intervals. The proposed rules do not require testing for added radioactive materials, like depleted uranium, which can be used in the perforation/fracturing operation. The proposed rules do not test work areas for levels of radioactivity that would call for OSHA standards of occupational safety. Rules §245.850(d)1-E and §245.850(e) are incomplete and deficient, and these inadequacies can "constitute a serious threat"--indeed, deadly threat-- "to the public interest, safety, or welfare" of Illinois citizens" and are in violation of section 1-75(a)(2) of the Hydraulic Fracturing Regulatory Act.

Sincerely, Colleen Dennis Chicago, IL 60605

The proposed rules do not require the testing of "produced water", which is the water produced from a well in conjunction with oil or natural gas production. This is where radioactivity is most likely to show up. It should be noted that while these Rules have been purported to be the strongest in the nation, PA law requires the testing of produced water at two separate intervals. The proposed rules do not require testing for added radioactive materials, like depleted uranium, which can be used in the perforation/fracturing operation. The proposed rules do not test work areas for levels of radioactivity that would call for OSHA standards of occupational safety. Rules §245.850(d)1-E and §245.850(e) are incomplete and deficient, and these inadequacies can "constitute a serious threat"--indeed, deadly threat-- "to the public interest, safety, or welfare" of Illinois citizens" and are in violation of section 1-75(a)(2) of the Hydraulic Fracturing Regulatory Act.

Sincerely, Emilio Joseph Comay del Junco Chicago, IL 60615

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Subsection (d)(1) of Section 245.850 provides for testing radioactivity only one time— during the early flowback stage—and only for "naturally occurring radioactive materials". The problems with this are identified below. Problems: The proposed rules do not include any standards or protocols to follow if testing of flowback water shows unacceptable levels of radioactivity. The proposed rules do not require the testing of "produced water", which is the water produced from a well in conjunction with oil or natural gas production. This is where radioactivity is most likely to show up. It should be noted that while these Rules have been purported to be the strongest in the nation, PA law requires the testing of produced water at two separate intervals. The proposed rules do not require testing for added radioactive materials, like depleted uranium, which can be used in the perforation/fracturing operation. The proposed rules do not require testing for added radioactive materials, like depleted uranium, which can be used in the perforation/fracturing operation. The proposed rules do not test work areas for levels of radioactivity that would call for OSHA standards of occupational safety. Rules §245.850(d)1-E and §245.850(e) are incomplete and deficient, and these inadequacies can "constitute a serious threat"--indeed, deadly threat-- "to the public interest, safety, or welfare" of Illinois citizens" and are in violation of section 1-75(a)(2) of the Hydraulic Fracturing Regulatory Act.

Sincerely, Jessica Green Chicago, IL 60637

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Subsection (d)(1) of Section 245.850 provides for testing radioactivity only one time— during the early flowback stage—and only for "naturally occurring radioactive materials". The problems with this are identified below. Problems: The proposed rules do not include any standards or protocols to follow if testing of flowback water shows unacceptable levels of radioactivity. The proposed rules do not require the testing of "produced water", which is the water produced from a well in conjunction with oil or natural gas production. This is where radioactivity is most likely to show up. It should be noted that while these Rules have been purported to be the strongest in the nation, PA law requires the testing of produced water at two separate intervals. The proposed rules do not require testing for added radioactive materials, like depleted uranium, which can be used in the perforation/fracturing operation. The proposed rules do not test work areas for levels of radioactivity that would call for OSHA standards of occupational safety. Rules §245.850(d)1-E and §245.850(e) are incomplete and deficient, and these inadequacies can "constitute a serious threat"--indeed, deadly threat-- "to the public interest, safety, or welfare" of Illinois citizens" and are in violation of section 1-75(a)(2) of the Hydraulic Fracturing Regulatory Act.

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Subsection (d)(1) of Section 245.850 provides for testing radioactivity only one time— during the early flowback stage—and only for "naturally occurring radioactive materials". The problems with this are identified below. Problems: The proposed rules do not include any standards or protocols to follow if testing of flowback water shows unacceptable levels of radioactivity. The proposed rules do not require the testing of "produced water", which is the water produced from a well in conjunction with oil or natural gas production. This is where radioactivity is most likely to show up. It should be noted that while these Rules have been purported to be the strongest in the nation, PA law requires the testing of produced water at two separate intervals. The proposed rules do not require testing for added radioactive materials, like depleted uranium, which can be used in the perforation/fracturing operation. The proposed rules do not test work areas for levels of radioactivity that would call for OSHA standards of occupational safety. Rules §245.850(d)1-E and §245.850(e) are incomplete and deficient, and these inadequacies can "constitute a serious threat"--indeed, deadly threat-- "to the public interest, safety, or welfare" of Illinois citizens" and are in violation of section 1-75(a)(2) of the Hydraulic Fracturing Regulatory Act.

Sincerely, Kathy Machaj Chicago, IL 60607

The problems with this are identified below. Problems: The proposed rules do not include any standards or protocols to follow if testing of flowback water shows unacceptable levels of radioactivity. The proposed rules do not require the testing of "produced water", which is the water produced from a well in conjunction with oil or natural gas production. This is where radioactivity is most likely to show up. It should be noted that while these Rules have been purported to be the strongest in the nation, PA law requires the testing of produced water at two separate intervals. The proposed rules do not require testing for added radioactive materials, like depleted uranium, which can be used in the perforation/fracturing operation. The proposed rules do not test work areas for levels of radioactivity that would call for OSHA standards of occupational safety. These deficiencies, cumulatively or singly, would pose a significant risk to the public health and safety, property, aquatic life, and wildlife, in violation of section 1-75(a) (2) of the Hydraulic Fracturing Regulatory Act.

Sincerely, Linda Green 422 East 450 North Rd MORRISONVILLE, IL 62546

The proposed rules do not require testing for added radioactive materials, like depleted uranium, which can be used in the perforation/fracturing operation. The proposed rules do not test work areas for levels of radioactivity that would call for OSHA standards of occupational safety. These deficiencies, cumulatively or singly, would pose a significant risk to the public health and safety, property, aquatic life, and wildlife, in violation of section 1-75(a) (2) of the Hydraulic Fracturing Regulatory Act.

Sincerely, Miranda Bailey 1822 Park Ave Alton, IL 62002

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Subsection (d)(1) of Section 245.850 provides for testing radioactivity only one time— during the early flowback stage—and only for "naturally occurring radioactive materials". The problems with this are identified below. Problems: The proposed rules do not include any standards or protocols to follow if testing of flowback water shows unacceptable levels of radioactivity. The proposed rules do not require the testing of "produced water", which is the water produced from a well in conjunction with oil or natural gas production. This is where radioactivity is most likely to show up. It should be noted that while these Rules have been purported to be the strongest in the nation, PA law requires the testing of produced water at two separate intervals. The proposed rules do not require testing for added radioactive materials, like depleted uranium, which can be used in the perforation/fracturing operation. The proposed rules do not test work areas for levels of radioactivity that would call for OSHA standards of occupational safety. Rules §245.850(d)1-E and §245.850(e) are incomplete and deficient, and these inadequacies can "constitute a serious threat"--indeed, deadly threat-- "to the public interest, safety, or welfare" of Illinois citizens" and are in violation of section 1-75(a)(2) of the Hydraulic Fracturing Regulatory Act.

Sincerely, Molly Blondell Chicago, IL 60637

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Subsection (d)(1) of Section 245.850 provides for testing radioactivity only one time— during the early flowback stage—and only for "naturally occurring radioactive materials". The problems with this are identified below. Problems: The proposed rules do not include any standards or protocols to follow if testing of flowback water shows unacceptable levels of radioactivity. The proposed rules do not require the testing of "produced water", which is the water produced from a well in conjunction with oil or natural gas production. This is where radioactivity is most likely to show up. It should be noted that while these Rules have been purported to be the strongest in the nation, PA law requires the testing of produced water at two separate intervals. The proposed rules do not require testing for added radioactive materials, like depleted uranium, which can be used in the perforation/fracturing operation. The proposed rules do not test work areas for levels of radioactivity that would call for OSHA standards of occupational safety. Rules §245.850(d)1-E and §245.850(e) are incomplete and deficient, and these inadequacies can "constitute a serious threat"--indeed, deadly threat-- "to the public interest, safety, or welfare" of Illinois citizens" and are in violation of section 1-75(a)(2) of the Hydraulic Fracturing Regulatory Act.

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Subsection (d)(1) of Section 245.850 provides for testing radioactivity only one time— during the early flowback stage—and only for "naturally occurring radioactive materials". The problems with this are identified below. Problems: The proposed rules do not include any standards or protocols to follow if testing of flowback water shows unacceptable levels of radioactivity. 1. The proposed rules do not require the testing of "produced water", which is the water produced from a well in conjunction with oil or natural gas production. This is where radioactivity is most likely to show up. It should be noted that while these Rules have been purported to be the strongest in the nation, PA law requires the testing of produced water at two separate intervals. 2. The proposed rules do not require testing for added radioactive materials, like depleted uranium, which can be used in the perforation/fracturing operation. 3. The proposed rules do not test work areas for levels of radioactivity that would call for OSHA standards of occupational safety. These deficiencies, cumulatively or singly, would pose a significant risk to the public health and safety, property, aquatic life, and wildlife, in violation of section 1-75(a) (2) of the Hydraulic Fracturing Regulatory Act. In case you do not appreciate the science behind flowback vs produced water. Flowback is the water that bounces back (so to speak) immediately after the high pressure frack. It comes back swiftly and in large quantities. But produced water comes up more slowly over the length of the mining operation. It comes up with the oil (or gas). This difference matters because the source of radioactive material is the shale itself. In particular the shale contains radium 226 and 228 which are water soluble. So the water which comes up slowly over time will be heavily saturated with the water soluble radium. And Southern Illinois shale is believed to have high radioactive content. But these provisions do not call for any testing of the produced water for radioactivity. That is a serious flaw in the rules

Sincerely, Richard Fedder Carbondale, IL 62901

The proposed rules do not test work areas for levels of radioactivity that would call for OSHA standards of occupational safety. These deficiencies, cumulatively or singly, would pose a significant risk to the public health and safety, property, aquatic life, and wildlife, in violation of section 1-75(a) (2) of the Hydraulic Fracturing Regulatory Act.

Sincerely, Ryan Pilcher 1531 N. Talman Ave #1 Chicago, IL 60622

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Subsection (d)(1) of Section 245.850 provides for testing radioactivity only one time— during the early flowback stage—and only for "naturally occurring radioactive materials". The problems with this are identified below. Problems: The proposed rules do not include any standards or protocols to follow if testing of flowback water shows unacceptable levels of radioactivity. The proposed rules do not require the testing of "produced water", which is the water produced from a well in conjunction with oil or natural gas production. This is where radioactivity is most likely to show up. It should be noted that while these Rules have been purported to be the strongest in the nation, PA law requires the testing of produced water at two separate intervals. The proposed rules do not require testing for added radioactive materials, like depleted uranium, which can be used in the perforation/fracturing operation. The proposed rules do not test work areas for levels of radioactivity that would call for OSHA standards of occupational safety. Rules §245.850(d)1-E and §245.850(e) are incomplete and deficient, and these inadequacies can "constitute a serious threat"--indeed, deadly threat-- "to the public interest, safety, or welfare" of Illinois citizens" and are in violation of section 1-75(a)(2) of the Hydraulic Fracturing Regulatory Act.

Sincerely, Samantha Martin Chicago, IL 60605

The proposed rules do not require testing for added radioactive materials, like depleted uranium, which can be used in the perforation/fracturing operation. The proposed rules do not test work areas for levels of radioactivity that would call for OSHA standards of occupational safety. Rules §245.850(d)1-E and §245.850(e) are incomplete and deficient, and these inadequacies can "constitute a serious threat"--indeed, deadly threat-- "to the public interest, safety, or welfare" of Illinois citizens" and are in violation of section 1-75(a)(2) of the Hydraulic Fracturing Regulatory Act.

Sincerely, Ta Promlee Chicago, IL 60645

In reference to Subpart H: High Volume Horizontal Hydraulic Fracturing Preparations and Operations

Section 245.850 Hydraulic Fracturing Fluid & HF Flowback Storage, Disposal or Recycling, Trans & Reporting Req.

Subsection (d)(1) of Section 245.850 provides for testing radioactivity only one time— during the early flowback stage—and only for "naturally occurring radioactive materials". The problems with this are identified below. Problems: The proposed rules do not include any standards or protocols to follow if testing of flowback water shows unacceptable levels of radioactivity. The proposed rules do not require the testing of "produced water", which is the water produced from a well in conjunction with oil or natural gas production. This is where radioactivity is most likely to show up. It should be noted that while these Rules have been purported to be the strongest in the nation, PA law requires the testing of produced water at two separate intervals. The proposed rules do not require testing for added radioactive materials, like depleted uranium, which can be used in the perforation/fracturing operation. The proposed rules do not test work areas for levels of radioactivity that would call for OSHA standards of occupational safety. Rules §245.850(d)1-E and §245.850(e) are incomplete and deficient, and these inadequacies can "constitute a serious threat"--indeed, deadly threat-- "to the public interest, safety, or welfare" of Illinois citizens" and are in violation of section 1-75(a)(2) of the Hydraulic Fracturing Regulatory Act.
